To Emmanuel, for everything he made possible

Preface

The Possible

As human beings, we live in the realm of the possible as much as we do in the here and now of daily experience. We dream, hope, anticipate, and create, continuously exploring new spaces of possibility for ourselves and for others. Our lives are marked by this “amphibious” state, dwelling in the real and the here and now, yet in constant engagement with the sphere of the possible, of what is not (yet) here and what could be (Glăveanu, 2020a). And it is precisely this kind of engagement that helps humans develop society and build complex cultures. The ability to entertain multiple possible outcomes is enabled by our propensity to use signs and symbols and, more generally, to engage with experiences of the world that are distant from what we perceive or what we do in the moment (Valsiner 2014). More than this, we have an unstoppable drive to expand what is possible in our lives and the lives of others. As individuals and as a species, we are keen to contemplate the limits of our possibilities for thought and action and then try to overcome them (Praszkier 2019).

A key concept within philosophy, psychology, and the social sciences at large, the possible designates that area of human experience that lies beyond the present, the sensorial, and the here and now. The possible is not opposed either to the “actual” or the “real” and, in fact, our capacity to engage with what is possible grows out of concrete experiences and ends up transforming them (Vygotsky 2004). It is imperative, thus, to transcend the long-standing dichotomy between the possible and the real. If we follow etymological roots (the Latin *possibilis* “that can be done,” from *posse* “to be able”), we discover this phenomenon is a precondition for human action. Instead of going beyond or contradicting reality, the possible grows out of and enriches our experience of the world by effectively enabling us to act in view of both how the situation is and how it could be (Baumeister et al. 2018). Thus, exploring the possible doesn’t take place outside of or beside our experience of the world: it infiltrates it from the start, infuses it with new meanings, and ends up transforming it altogether. At the same time, the possible should not be reduced to the common-sense notion of what is not certain or what is probable. This would invite a discussion of it mainly in terms of probabilities, counterfactual thinking, and predictions of the future. While a lot of what we refer to as possible belongs to the immediate or distant future, engaging with the possible can be

equally about the past, the elsewhere, the unseen, and the impossible itself (see also Glăveanu 2018).

Another important aspect to note from the start is that possibilities are not always appealing or exciting. Having too many options to choose from can be disorienting (Scheibehenne et al. 2010), innovating in unsustainable ways harmful (Röpke 2012), and spending time in virtual reality can reduce the appetite for in-person encounters (Williams 2007). On the one hand, this quest for actualizing potentialities reveals the best and brightest in human nature and is arguably behind our most creative and innovative achievements. But, on the other, it carries risks and dangers; not everything we imagine as possible should become reality, not all possibilities lead to the common good. In fact, as the state of the world today demonstrates – in environmental, social, economic, and political terms – enacting some potentialities closes the door on other possibilities, expanding the possible for some can mean reducing it for others and, thus, ethical choices need to be made at every turn (Sternberg 2021). Engaging with uncertain outcomes requires these choices be made in the absence of guarantees about the eventual result. In the context of the (post) pandemic world, it becomes imperative to have a sustained reflection about the nature of human possibility, its origins, processes, and consequences. This is the mission of what we currently identify as a “possibilities turn” and the emerging field of Possibility Studies – the rich background for the present encyclopedia.

The Possibilities Turn

The ability to mobilize what is absent in order to enrich the present has been intensively studied within a variety of disciplines across history. These include, but are not reduced to, psychology, philosophy, education, futures studies, sociology, management, business, developmental science, anthropology, politics, design, and the arts. The vocabulary of the possible and the processes assumed to contribute to its cultivation are equally numerous. There is today an expanding field of research on creativity, imagination, innovation, and anticipation, a pervasive interest in counterfactual thinking, as-if thinking and wondering, and, more broadly, in phenomena like hope, agency, and utopia. What drives this concern is both an age-old question about the psychological functions that underpin the development of human forms of culture and civilization and a renewed interest in the power of creativity and imagination to help us solve the numerous, pressing challenges we are faced with as individuals and societies. This interest, and the challenges that trigger it, are both new and old, and a short detour through time can help us understand better where the possible “fits” within this history and what it can bring about.

There is no single scientific account about our humanity, but an ongoing story we create and constantly challenge through multiple paradigmatic turns. For example, the narrative turn of the 1970s and 1980s began in semiology and literary studies and soon after led the ongoing constructionist movement that made social scientists pay closer attention to language, culture, and context (Berger and Luckmann 1989; Bruner 1991). This emphasis on text and

language left many dissatisfied, however, especially those concerned by objects, places, and materials. Socio-materiality emerged in the 1990s and early 2000s as a new paradigm aimed at recognizing the relational nature of our existence, embedded as it is in systems that are, at once, social and material (Latour 2005; Leonardi 2013). After the 2000s, the new mobilities turn responded to yet another perceived limitation of focusing mainly on objects, places, and institutions – their depiction as static or, at least, seemingly static. This latest paradigmatic approach depicts the world in flux and continuous movement (Urry 2016).

Underpinning most of these developments is an interest in possibility, its antecedents, processes, and consequences. The narrative turn brought into sharp focus the potential of language and culture to expand our experience of the here and now. Socio-materiality redefined agency by recognizing objects as actants. Mobilities helped us reflect on how a world in movement is also one that is constantly changing (e.g., Glăveanu 2020b).

There are other fields of research that developed since the 1950s to contribute substantially to our understanding of possibility and its limits. For example, Futures Studies, an area with deep historical roots, emerged as an academic discipline mid 1960s, opening up new spaces for thinking about the future and the processes through which we envision it (Bell 2017), from prediction to forecast and foresight (central topics for a more recent area of inquiry called anticipation studies; Poli 2017). The interest in imagination is centuries old and, during this long time, the importance granted to this process has waxed and waned (Kearney 2002). The past decades “re-discovered” this phenomenon in a variety of disciplines, from philosophy to psychology and neuroscience. Most of all, research into creativity consolidated into a scientific discipline after the 1950s and is today a blooming area of study featuring several dedicated journals and a variety of books, handbooks, and encyclopedias (e.g., Kaufman and Sternberg 2010; Kaufman et al. 2017).

These and other developments mark the start of a “possibilities turn” within the human and social sciences, a turn that is not only announced by increasing levels of research into possibility-related phenomena, but also by the evolution of society in the twenty-first century. From speedy advances in ICT and virtual reality to new technologies that revolutionize transport, medicine, and design, we live in a day and age that opens new horizons of possibility for individuals and societies alike while, at the same time, revealing serious dangers and unintended consequences (from the alarming rise of misinformation on social media to the dramatic consequences of climate change; de Saint-Laurent et al. 2017; Goeminne 2012).

In this societal and scientific context, the area of Possibility Studies concerns itself with the triggers, processes, and outcomes of engaging with the possible at a psychological, material, technological, sociocultural, and political level. It offers, thus, a wide, interdisciplinary umbrella for a series of either well-established or more recent fields of research including creativity, innovation, imagination, wonder, serendipity, pretend play, counterfactual thinking, the future, anticipation, utopias, and social change, among others. The great advantage of placing these domains within a broader “turn” is the fact that research on the possible becomes interdisciplinary by necessity, encouraging

dialogues across the natural and social sciences, the arts and humanities, theoretical and applied fields.

In order to capture this openness and inclusivity, the possible is broadly defined as those features, processes, and events that can come into being and transform what already exists. In other words, beyond the here and now of concrete experience, possibilities designate the elsewhere, the not yet here and the nowhere that, through anticipation, imagination, and creativity, shape how individuals and communities think, feel, and act in the present and build a future. This is not a romanticized understanding of the possible, but a critical reflection on who, how, what, when, where, and why we strive towards possibilities and impossibilities. This ethos substantiates Possibility Studies and its many potentialities.

Possibility Studies

As argued above, Possibility Studies is an emerging, interdisciplinary field of study with a long past but a short history. The theme of human possibility is as old as our reflections about human nature and our place in the world. For centuries, answers to questions related to how we discover and explore possibilities have been offered by philosophers, theologians, and natural scientists. From the nineteenth and twentieth centuries onwards, these interrogations came to be placed mostly at the intersection between the humanities, social sciences, and the arts (but not only, see Olson 2016). Nowadays, calls to take into account themes such as the future, hope, anticipation, creativity, and imagination, among others, are frequent across psychology, sociology, anthropology, and connected disciplines. A paradigm shift is underway in all these fields, built on the background of the multiple emergencies we are faced with, from climate crises to the challenge of “post-truth,” accentuated by the impossibilities brought about by the COVID-19 pandemic.

Briefly defined, Possibility Studies aims to advance our theoretical and practical understanding of how individuals and collectives become aware of and explore new possibilities in the realm of the psychological, material, technological, social, cultural, and political. It brings together research on agency, creativity, innovation, imagination, improvisation, serendipity, wonder, hope, utopias and dystopias, anticipation and Futures Studies, counterfactual thinking, and all other phenomena that focus on our engagement with what is possible (and impossible) in our existence. This kind of research is necessarily interdisciplinary, and one of the main benefits of bringing them together under the umbrella of Possibility Studies rests in the potential for cross-fertilization and, with it, the development of new theories, methodologies, and practices that can help us study and advance human possibility in an age that urgently calls for such an endeavor.

As a large-scale interdisciplinary movement, this area of research brings together scholars and practitioners from a variety of fields that span the social and natural sciences and put them in contact with the arts and humanities. Questions about human nature and possibility have been central to theological and philosophical thinking since their inception. Explorations of what it means

to have agency and be endowed with imagination are inscribed within humanistic thought and currently redefined by post-humanism in the direction of recognizing that materials can also be actants. Psychologists dedicate more and more time to themes like creativity, serendipity, and chance in trying to overcome simple and deterministic models of human behavior. Sociologists and economists bring these interrogations to the level of society and highlight the pressing need to reimagine institutions and economic principles. Entire disciplines have been formed around the theme of the future and its pull, both old (Futures Studies) and new (anticipation studies). Meanwhile, the arts have continuously attempted to open up new spaces of dialogue and possibility when it comes to our understanding of the world and our place within it.

The main challenge facing this growing, diverse community is the lack of systematic opportunities to meet and engage with each other's ideas. While the centrality of the theme of human possibility is recognized across several disciplines (e.g., Appadurai 2013; Gergen 2015; Tavory and Eliasoph 2013), academics are often trapped by disciplinary siloes of concerns and vocabularies that do not communicate effectively with each other. This lack of cross-fertilization restricts progress in fields like creativity which crosses several domains such as psychology, anthropology, design, and philosophy with little transdisciplinary collaboration. For example, psychological research is often based on the study of individuals while the literature on social change is typically focused on macro-social and institutional transformation – theories and findings from both could cross-fertilize in building frameworks of “collective possibility,” but this is a dialogue yet to take place.

We also have, across disciplines, different terms that capture very similar phenomena but tend to do so from particular angles. For instance, constraints are an important notion for innovation and improvisation researchers, but they tend to have a negative connotation in the former (e.g., among innovation management scholars) and positive in the latter (e.g., among anthropologists). However, I believe that it is precisely in the difference of perspectives that understanding can grow. The purpose of creating a space of dialogue on human possibility for experts coming from a variety of fields is not to reach consensus about the topic as this would deny precisely the kinds of differences that are the engine of possibility itself; it is to create opportunities for transdisciplinary collaboration, breakthrough research, and for raising the big questions of Possibility Studies.

The Present Encyclopedia

In this context, the Palgrave Encyclopedia of the Possible aims to examine this central notion and the numerous concepts and themes associated with it today from the standpoint of various disciplines (e.g., psychology, philosophy, sociology, neuroscience, logic, design, ergonomics, entrepreneurship) and multidisciplinary fields of research (e.g., anticipation studies, future studies, complexity theory, creativity research). It adopts multiple perspectives on the possible, from developmental (e.g., considering its emergence in pretend play and games, in the use of symbols and technology) to applied (in domains such

as the arts, architecture, design, and business). It focuses on how we explore the possible (e.g., possibility thinking, wondering, anticipation), as well as how we cultivate it in everyday interactions and within society (e.g., in education, social change, culture). Last but not least, it includes entries that discuss the work of eminent scholars who made important contributions to the areas mentioned above (e.g., Dewey, Lacan, Bakhtin, Winnicott).

The Palgrave Encyclopedia of the Possible offers readers a comprehensive overview of the main concepts and debates within this multifaceted area of research situated at the interface between multiple disciplines and having clear implications for education, business, and society. This book aims to make a significant contribution to our understanding of what the possible is, when it emerges in our everyday life, what kind of processes participate in becoming aware of the possible and exploring it, and, last but not least, what are the consequences of engaging with the possible for our individual and collective existence. It provides conceptual, methodological, and practical tools for all those interested in studying possibility and cultivating it through education and within society.

While studies of the possible do not represent a unitary and homogenous field, it is both important and timely to gather and systematize the vocabulary of this emerging, multidisciplinary area of research within an Encyclopedia. My hope is that this project will not only give researchers interested in Possibility Studies access to a key resource for their work, but it will also bring together and consolidate a community of scholars focused on how we explore, mobilize, and foster the possible within a variety of theoretical, research, and applied contexts. It stands as an open invitation to co-construct the field and its future.

Acknowledgments

The editor would like to express his deep gratitude to all the colleagues at Palgrave who supported this project from the start and made it possible. His gratitude also goes to the excellent team of senior editors who generously dedicated their time and ideas to curate such a diverse and rich type of content, and to the authors who provided such insightful pieces. Last but not least, the community of possibility studies scholars, researchers, and practitioners needs to be acknowledged – this encyclopedia is a landmark in its development, now and in the future.

About the Editor

Vlad P. Glăveanu PhD, is Full Professor of psychology in the School of Psychology, Dublin City University, and Professor II at the Centre for the Science of Learning and Technology, University of Bergen. He is the founder and president of the Possibility Studies Network (PSN). His work focuses on creativity, imagination, culture, collaboration, wonder, possibility, and societal challenges. He edited the *Palgrave Handbook of Creativity and Culture* (2016) and the *Oxford Creativity Reader* (2018); co-edited the *Cambridge Handbook of Creativity Across Domains* (2017) and the *Oxford Handbook of Imagination and Culture* (2017); authored *The Possible: A Sociocultural Theory* (Oxford University Press, 2020), *Creativity: A Very Short Introduction* (Oxford University Press, 2021), and *Wonder: The Extraordinary Power of an Ordinary Experience* (Bloomsbury, 2020); and authored or co-authored more than 200 articles and book chapters in these areas. Dr. Glăveanu co-edits the book series Palgrave Studies in Creativity and Culture with Palgrave and the Cambridge Series on Possibility Studies with Cambridge University Press. He is editor of *Europe's Journal of Psychology* (EJOP), an open-access peer-reviewed journal published by PsychOpen (Germany) as well as *Possibility Studies and Society*, launched by Sage in 2022. In 2018, he received the Berlyne Award from the APA Division 10 for outstanding early career contributions to the field of aesthetics, creativity, and the arts.

Abduction

Gabriel Fortes

Department of Psychology, Universidad Alberto Hurtado, Santiago, Chile

Abstract

In general, Abduction refers to a logical operation of explanatory reasoning out of a specific set of premises, both discovery and hypothesis formulation. Abduction has also been referred to as various reasoning processes, such as hypothetical thinking, imagination, intuition, and guessing. Despite its variety of definitions, the leading intellectual reference for this entry is Charles Sanders Peirce (1839–1914), logician and American philosopher, who first developed abductive reasoning ideas. We aim to understand what Abduction refers to and its impact on human knowledge construction, especially how it conceptualizes that humans are “made for” dealing with the possible. In this sense, an Abduction is a human form of coping with plausible possibilities and not with certainty or probability in logical terms. We will point out how to use the idea of Abduction in different ways and how it supports different ways of dealing “rationally” with the possible (be it as uncertainty, prediction, novelty, guessing, or intuition). We will discuss how this inclination toward dealing with uncertainty is not a process of truth-seeking but

exploring possible worlds within the available information for each one in a given context (Ribeiro et al., Uncertainty in decision-making: an abductive perspective. *Decision Support Systems* 13(2):183–193, 1995). This type of reasoning has been explored in logics and scientific discovery, in learning contexts, and in ordinary life, to mention a few. With all of the above mentioned, we should understand Abduction as a critical process of human grasping of the possible.

Keywords

Abduction · Abductive Reasoning · Surprise · Charles S. Peirce

Introduction

Before we begin with Abduction, we must first understand why it is considered different reasoning compared to deduction (drawing a true conclusion from valid premises) and induction (inferring a probable conclusion from available information). Charles Sanders Peirce first noticed that deduction and induction were not sufficient logical procedures (Peirce, CP 1.559, 1867) to account for how one makes inferences in the context of insufficient information available. (We will use the standard notation for Peirce’s work, *Collected Papers* (1931–1958), by volume and paragraph number. References to “MS” are to

Peirce's Manuscripts (1963–1966) by paragraph number.) In his work, deduction refers to the logical operation of deriving necessary conclusions from given premises, induction refers to the procedure of inferring general rules from multiple observations, and Abduction refers to generating a hypothesis given a context of insufficient information or uncertainty. Following Peirce, Thagard (2007) proposes the following notation for Abduction: q , if p then q , so maybe p . Peirce named this process of thinking through “maybes” differently throughout his work, as Abduction, retrodution, hypothesis, or hypothetical inference (Bergman and Paavola 2003; El Khachab 2013), but the consensus is that Abduction refers to a reasoning procedure of inferring plausible explanation from surprising observations.

One of Peirce's main idea on Abduction is that one cannot achieve novel knowledge without a mechanism of hypothesis formation; it is only through “maybes” that we grasp for novelty. In other words, Abduction is a mode of reasoning responsible for the generation of momentary truths. In our interpretation, Abduction is a vital part of how the possible unfolds through human reasoning.

The Development of Abduction

There are at least two phases of Peirce's ideas on Abduction (and its many forms) accepted in literature. It is common to distinguish between an early (1860–1890) and late (1890–1910) Peirce (Paavola 2006; El Khachab 2013). Although both deal with Abduction under the basis of logical and psychological investigation of inference, they differ significantly on width and application to the idea of the possible.

In his earlier works, Peirce emphasized establishing the logical grounds for this new mode of reasoning. Drawing from the logical procedure of syllogistic reasoning, he proposed that Abduction is the inference of causes from effects in the best possible explanation. While deductions produce true knowledge and induction produces probable knowledge, Peirce revealed that we have grounds to warrant a

mode of reasoning of plausible knowledge, which is a revolutionary idea if we want to understand how new ideas arise from existing knowledge. In Peirce's understanding, no one can construct new knowledge under validity or probability modes of inference.

Despite the emphases on logical grounds of Abduction, Peirce's later work dives more in-depth into Abduction than his first stage of inquiry or discovery (El Khachab 2013; Hintikka 1998). Although not abandoning his tendencies of pursuing logical soundness, what seems to be at stake in this phase is how Abduction is the foundation of human reasoning. Even though he says that Abduction (or hypothesis) is a weaker form of inference, it serves as the mechanism in generating new ideas. For him, Abduction is the process by which we formulate momentary good reasons to adopt a new hypothesis that then should be tested later through induction (Hintikka 1998; Walton 2014). In this sense, he takes Abduction as the tendency of finding an explanation for puzzling or surprising information, as he formulates the following:

1. The surprising fact, C , is observed.
2. But if A were true, C would be a matter of course.
3. Hence, there is a reason to suspect that A is true. (Peirce, CP 5.189, 1903).

Peirce takes it seriously when stating that Abduction seems to be a tendency of the human mind to deal with puzzlement. He further states that the process of guessing is not only logical but instinctual (Santaella 1991; Tschaepé 2014). By instinct, he means the capacity for guessing without the need for deliberative reasoning. For Santaella (2005), this idea is both revolutionary and controversial because it states that humankind has a natural tendency (even unconscious) for correctly guessing what, many times, excels our conscious effort of deliberative reasoning.

For Philosophy and Psychology, this means that neither empiricist nor rationalist understanding of human cognition is complete. Moreover, it means that new knowledge depends upon processes often uncontrolled by a rational

mind, however, still grounded on logical processes. Although Peirce's first ideas are interesting for the discussion of the possible, we find this second version even more critical because this idea of Abduction operationalizes how we imagine, amplify, and create our possible within the realms of rational tendencies of dealing with uncertainty.

This instinctive and natural capacity for generating possible explanations should not be taken as a "truth-seeking" mechanism but as a creative (and innovative) reaction to surprise and puzzlement (Paavola 2005). Peirce's work often interconnects words such as surprise, puzzle, curiosity, guessing, or discovery with the idea of the abductive process of inference. In our interpretation, especially when thinking about the possible, Peirce is more interested in abductive reasoning products in his first phase. Even when he uses the term "inference process," knowing its results (rules, facts, and cases) is at stake. His second phase, more interesting for us, is concerned with the human condition of regularly dealing with uncertainty and, almost always, succeeding in dealing with it "rationally." Peirce's second phase is the most prevalent today when scholars think or speak about Abduction; however, after Peirce, much work has been done to conceptually and empirically advance the idea of Abduction and its role in human life.

Further Advances on Abduction

Much of the conceptual work on Abduction has been developed in the writings of Peirce; however, much of the contemporary understanding of abductive reasoning (and its manifold) is also due to further development in different fields of expertise: philosophy and logics (Hanson 1972; Anderson 1986), psychology and cognitive sciences (Thagard and Shelley 1997; Magnani 2009), linguistics and literature (Eco and Sebeok 1983), and many others. In this section, we review the ideas that helped to advance the concept of Abduction and how it relates to the idea of the possible, but, as pointed out before, we will privilege ideas that depart from Peirce's second phase because we

assume it as closer to our purpose of addressing the possible through the lens of Abduction.

One well-known development to Peirce's ideas on abductive reasoning is the work of Norwood R. Hanson in the *Patterns of Discovery* (Hanson 1972). Hanson's contribution on Abduction is mostly related to the philosophy of science, especially to scientific discovery. From Peirce's ideas, we can point to significant inspirations: how to create a new hypothesis through the feeling of surprise or puzzlement (VenuKapalli 2013) and that "backward" reasoning is a step from surprise to explanation (Paavola 2006). In a very Peircean fashion, Hanson's proposition is as follows (Hanson 1972, p. 86):

1. Some surprising or anomalous phenomenon "P" is observed.
2. "P" would be explicable as a matter of course if "H" were true.
3. Hence, there is a reason to think that "H" is true.

This set of claims was often criticized due to the "lack" of soundness (Plutynski 2011). However, for our purposes, this is an astounding achievement in the philosophy of science. This simple syllogistic construction allows us to reflect upon the fact that knowledge construction depends on the observer's constructive and active role in coordinating previous knowledge, observed strangeness (most times related to a feeling or confusion), and a plausible momentary truth giving us tools to operationalize how new knowledge emerges in different contexts, although Hanson has described it mainly on scientific discovery methods.

As Peirce had proposed before, all human inference must come from a natural tendency to deal with information. Scientific thinking is just a complex form of our regular capacity to inference applied to a specific field of knowledge "... all human knowledge, up to the highest flights of science, is but the development of our inborn animal instinct" (Peirce, CP 2.754, 1903). With this, we move forwards into conceptualizing Abduction as the "natural" and "inborn" inferential move of creating "if-true" possible

knowledge. In other words, this accounts for the plausible (and possible) as a momentary truce. Although not a consensus, we remark that within this “model” of discovery, the importance does not rely on data itself but subjects’ reactions. For us, this is a big step into developing a theory of knowledge based on feelings, reactions, and human agency, contrary to data-driven, logical soundness and truth-seeking.

This humanistic understanding of knowledge construction under uncertainty is not bullet-proof to criticism. One criticism of this “broader” idea of Abduction points out that hypothetical thinking must be inferred within the existing premises. Hence, it is not new knowledge. In this sense, Abduction is not sufficient to propose a discovery model (Kapitan 1990). Moreover, as Paavola (2004) pointed out, this criticism sought to distinguish between rational inference and what Peirce accounts for as guessing or instinct. As points Santaella (2005) in Peirce, we can find this distinction. However, this does not diminish the importance of the second one in favor of the first one. On the contrary, this shows that there is more to reasoning than formal logic.

In fact, in modern logic and argumentation theory, Abduction refers to what Gilbert Harman postulates as “inference to the best explanation” (Harman 1965). This model Abduction refers to a subtype of inductive inference that warrants us to logically eliminate alternative explanations to a set of premises (empirically observed or logically formulated). In this sense, Abduction is the process of finding the most probable (or better suited) explanation to a given observation under the available information. Although not directly related to Peirce’s notion of Abduction (especially the second Peirce), this model also allows us to reflect that “the possible” is always part of the knowledge construction processes. It shows us that even under formal logic interests, we cannot escape that uncertainty (or lack of information) drives human minds to a possible that we must accept as an open-to-discussion truth.

The advances in Abduction are not limited to logic or the applied fields of logical propositions. In the investigation, the “methods” of Sherlock Holmes and C. Auguste Dupin, Umberto Eco, and

Tomas Sebeok (1983) argue for a compelling case that the logical methods prescribed in investigative literature were “creative” Abduction (not deductive as most times they are referred to). Their book goes further into the idea that Abduction is always present in the human mind. It is part of the fabric of our cognition. Their several chapters book makes a remarkable work in presenting how to integrate clues and imagination into “quasi-logical” guessing procedure, brilliantly present in Arthur Conan Doyle and Edgar Allan Poe’s novels.

One significant contribution taken from this is how Eco and Sebeok (and many other contributors to the book) recall the importance of semiotics in comprehending Peirce’s logical operation ideas. In this sense the capacity of Abduction to infer signs from signs to make up possible interpretations in a sign-mediated reality, resulting in a big step because the realm of logical validity and truth-seeking frequently claims Abduction. Reclaiming it to the semiotic domain highlights the importance of context, language, and imagination for human “sense-making” of the world.

To sum up the after-Peirce advances on the concept of Abduction, we refer to Thagard’s (2007) four quasi-logical models in Peirce’s ideas: (1) simple hypothetical inferences from objects, (2) existential Abduction, that postulates knowledge to exist in the absence of fact to back it, (3) rule-forming Abduction, a vital inference procedure in theory generation (rules that explain other rules), and (4) analogical Abduction, an inference that uses past cases (or experiences) to further formulate a more complex hypothesis. These four quasi-logical models are a useful description of achievements made by using Peirce’s ideas. Moreover, Aliseda (2006) proposes a simpler version account for Abduction as referred to three levels of inference: (1) a logical parameter involved in formulating explanations (possibility, plausibility, derivability, and others), (2) those “triggers” for new knowledge formulation (e.g., puzzlement and surprise), and (3) the products of abductive reasoning (facts, rules or theories). Although not exhaustive, these two summaries are good descriptions of the uses of

the concept of Abduction throughout different domains of knowledge. However, we still have to make it clear how Abduction and the possible come together.

Abduction and the Possible

For Peirce (and most scholars in this field), the starting point in Abduction must be the feeling of puzzlement, in his particular interpretation (and neglected by others), the central importance of emotion in this mode of reasoning, as astonishment and surprise are both significantly related to emotions and abductive inference in real-world situations (Thagard 2005). In a certain sense, Abduction can be interpreted as a reaction to surprise that enables the formation of the possible, a step toward amplifying what is known through concluding something useful or new (Hintikka 1998).

This tendency to plausibility allows us to infer that Abduction is the process of creating new knowledge based on feeling and intuition (Paavola 2005). Moreover, this tendency varies in degrees of plausibility. As Paavola (2006) says, it goes from “a question meriting attention” to an “uncontrollable inclination to believe.” Abduction tends to create the possible, and for Peirce, this means a possible that obeys the laws of nature and reflects rational human capacities. This “guessing” instinct of reasoning (Santaella 2005) Peirce often points out to be correct and reveal logical goodness (El Khachab 2013). However, weak in form, this type of inference is powerful in creating plausible realities that give texture to everyday life affairs.

The possible interpreted through the lens of Abduction refers to new, if-true, maybe, almost logical construction of (not yet known) knowledge. For that reason, many scholars have described Abduction as a discovery method (Hanson 1972), a starting point for novelty in science (Thagard 2005), the logical requirements to deal with uncertainty (El Khachab 2013). Most importantly, Abduction is interpreted as something that constrains and fosters searching for new ideas (Paavola 2006).

In the following sections, we present three examples of Abduction in different contexts. First, we discuss how abductive modes of reasoning enable scientific discovery and explanation. Second, we present how the application of Abduction-inspired classroom practices fosters imaginative, exploratory, and innovative knowledge construction for students. Third, we present how Abduction is part of how we make up our understanding of everyday life, focusing on how this inference mode is much more present than one would imagine.

Abduction and the Possible in Scientific Discovery

Our departure point for this section refers to Peirce’s own words: “Every single item of scientific theory which stands established today has been due to Abduction.” (Peirce, CP 5.172, 1903) As Gare (2020, see entry ► “[Speculation](#)”) points out, scientific discovery is achieved through speculation because it depends on imagining creative solutions to contradictions, limitations, blind spots, and paradoxes. Moreover, Wilkie (2021, see entry ► “[Speculative Research](#)”) points out that when this type of investigation is in place, one in which we are dealing with surprising or uncertain objects, we are launched into the realm of the unexpected, novel, and “possibilistic.” We go further; what scientists are asked to do is make a possible, acceptable, useful, and plausible knowledge, even if it is not a self-evident truth. To present our case, we use the example of Johannes Kepler’s postulate of Mars’ orbit famously discussed by Peirce.

Kepler’s case is quite famous among scholars who study Peirce’s work. Peirce (CP 2.96, 1902) says that when observing the orbits of the planet Mars, they behave as if they were elliptical. Note that this as-if thinking made Kepler so inclined to this conclusion that he applied (or created) a model to verify if it was also true for the other planets and parallaxes observed in the data. Kepler’s discovery is an abductive move in Peirce’s notion not because he found the right

answer but because he found it through feeling inclined to something and then tested it afterward. This discovery is now used to discuss several points: new knowledge is not the result of a single person's genius (Hanson 1972), to exemplify the rational process of finding an explanation to surprising data (McKaughan 2008) and how creative and inventive processes of analogy do scientific thinking (Kapitan 1990; Gentner 2002). In this case, the Possible results of a constructive process of feeling and pursuing an intuition, what Magnani (2009) calls "creative Abduction."

Abduction and the Possible in Teaching and Learning

Educational settings are fruitful spaces for reasoning processes to emerge, develop, and establish within social practices of learning. Deduction or induction base most of what is said about teacher and students' reasoning in classroom activities. The first one accounts for formal procedures of reasoning based on syllogistic truth-seeking methods, mostly concerned with necessary truth conditions for knowledge. The second one refers to learning based on generalizations from data, especially in the learning of natural sciences. These practices look for true, valid, and accurate scientific concepts.

However, a very current student practice, but less conceptualized or even explored as useful, occurs when students explore knowledge through different alternatives, promoting as-if statements that defy consolidated and normative school knowledge. Haig (2012) calls it abductive learning when applying different forms of abductive reasoning to different learning activities that ask students to formulate explanations and test hypotheses for an observed phenomenon.

In a different direction, other researchers address the abductive processes in education in a broader sense. For Rapanta (2018), active methodologies that rely on engaging classroom discourse, such as argumentation, actually foster abductive reasoning and not formal logic or possible generalizations. In other words, that what we ask our students to do when using discourse such

as argumentation is to explore possible alternatives to explain, advance, reject, or strengthen an opinion based on coordinating previous and new knowledge. Moreover, Larrain (2017) argues that deduction and induction are insufficient to explain the development of concepts. There must be a mechanism responsible for anticipating, reviewing, and reorganizing new knowledge. In this sense, she says that formulating and evaluating the (im)plausibility of something revolves around imagination. For concept development and learning, then, imagination is necessary because it moves the here-and-now knowledge to surpass borders not yet known.

In the same spirit, one example of this approach to learning processes is Macêdo's (2021) work observing university students discussing personality development theory in Psychology. In this work, the author presents how students frequently engage in the "if-true, then. . ." type of reasoning using different psychological concepts in order to make sense of the concept of gender transition, without instructions to do it in this particular way. Initially, the case seems to be a rather traditional deductive inference structure "if. . . then. . ." However, we point to the use of an if-like type of discourse meant to expand the boundaries of the concepts in order to evaluate what they did apply for or not; in other words, the students were not making deductive movements trying to infer an existing conclusion, they were actually proposing best possible explanations if the use of personality would apply or not to a variety of situations. For the students engaged in the conversation, it was essential to see if the role of nature and nurture in the constitution of personality implied what notion of transformation and to what extent this transformation would be conscious or voluntary. With different scenarios and creating possible worlds, the students were able to coordinate, assess, and formulate different positions that could be plausible through "as-if" thinking; they were experimenting with the plausibility of concepts and not with certainty of them. Even when engaging wrongly with some canonical concepts, this "if-true" "maybe" reasoning allowed them to move forward the boundary of the concepts discussed.

Unlike conditional thinking, we highlight here that the imaginative, creative, momentary theory construction made it possible for the students to engage critically in the subject-matter in a way traditionally they would not be able to.

Abduction and the Possible in Ordinary Life

While the two before mentioned examples speak of effortful and deliberative processes (at least as part of scientific discovery or learning), we now address a relatively fast and uncontrolled interpretation of Abduction (Thagard 2005, 2007; Magnani 2015). In many interpretations, Abduction is the process of discovering or unveiling “existing” knowledge, or at best, bringing to light hidden information through a weaker form of inference (Paavola 2006). That is mostly due to the impact of Peirce’s ideas on logic and the philosophy of science. However, when considering how the later Peirce relates to contemporary psychology of reasoning, and even cultural psychology, the boundaries of Abduction are stressed to limits outside formal logic and thrown into the human mind relation to reality, what many logicians worry as “psychologism.” Now, we address how Abduction shapes (not discovers) our reality. We aim to show that Abduction is part of everyday life as a vital and concrete experience (Nubiola 2005) of making the “best possible” out of our previous knowledge (or ignorance).

Magnani (2015) proposes that abductive reasoning is a type of response to ignorance-problems. Ignorance (see entry ► “Ignorance”) is taken as uncertainty, puzzlement, or unexpected knowledge demanding situation (we could risk stating that all situations are these in nature). Moreover, he proposes that Abduction is an ignorance-mitigating type of reasoning, meaning that there are other less useful types of responses (non-mitigating) and that abductive reasoning is a large part of how our cognition handles reality. He proposes that ignorance-problems triggers one of three types of responses: (1) ignorance overcome due to additional knowledge necessary in that context, (2) acceptance and surrendering to

ignorance (or at least partially), and (3) ignorance is used as the basis for new knowledge, in this sense, we abduce from constitutive ignorance. Magnani’s work is an essential step in developing a theory on how we deal with uncertainty through abductive means while creating new knowledge that helps us surpass situational ignorance, be it at decision making, professional practices, or art appreciation.

On the presence of Abduction in our lives, Thagard’s (2007) view helps us understand the role of emotion and intuition in our rationality. Most of what is made from Peirce’s ideas on Abduction is related to the logical strength of this mode of reasoning. However, Thagard (2007) says that one missing point is that even in Peirce’s work, Abduction departs from and arrives at emotional states. For him, the process of Abduction starts at the feeling of puzzlement and ends at the satisfaction of knowing. This concept is vital because it reclaims the role of psychological processes in our understanding of the world.

Following Peirce’s idea of “[...] the perceptual judgments, are to be regarded as an extreme case of abductive inference” (CP, 5181 1903), Thagard (2007; Thagard and Shelley 1997) presents an interpretation of Abduction related not only to logical and verbal acts of reason but as part of our forms of inferring the surrounding reality. For him, Abduction is a multimodal type of inference that coordinates our emotional reaction and guides us to the satisfaction of finding plausible knowledge.

This interpretation is not only well described but originates from Peirce’s own words. Now we look at an example of how abductive inference is part of the ordinary experience of everyday life events in Peirce’s words:

Looking out my window this lovely spring morning I see an azalea in full bloom. No, no! I do not see that; though that is the only way I can describe what I see. That is a proposition, a sentence, a fact; but what I perceive is not proposition, sentence, fact, but only an image, which I make intelligible in part by means of a statement of fact. This statement is abstract; but what I see is concrete. I perform an Abduction when I so much as express in a sentence anything I see. *The truth is that the whole fabric of*

our knowledge is one matted felt of pure hypothesis confirmed and refined by induction. Not the smallest advance can be made in knowledge beyond the stage of vacant staring, without making an Abduction at every step. (MS 692, 1901 – our emphasis)

This idea of Abduction allows us to conclude that our reality is a recurrent process of guessing and readjusting our knowledge to our senses. In this sense, the possible is not discovered or is a probable event. The possible, interpreted through this amplified idea of Abduction, is the reality in itself, and the process to construct (not discover) is abductive, fast, and uncontrolled inference. With this example, we point to the accomplishment of Peirce in presenting (or reviewing) how our current state of real worldliness is momentary and conformed by our best possible knowledge in a given context.

Conclusion

We aimed to present how Abduction is developed in Peirce's early and late phases with this entry. Following the latter, we discuss how the possible is only ever realized in life because of this peculiar mode of reasoning. Abduction, then, should be viewed as a natural modality of inferences that has two sides to it: on the one hand, it can be developed through effortful and deliberate reasoning, and on the other as a fast and uncontrolled inference that shapes our perception of reality. The first mode of reasoning is generally applied to the possible as a scientific discovery, justified guessing, and useful explanation that helps foster novel knowledge (be it at scientific or classroom level). The second mode, less formalized but more pervasive, is mostly used in the perceptual investigation and everyday life understanding, primarily relating to how we actively construct our reality. Both of them derive from surprise and puzzlement, and for this reason, Abduction is a particular case of reasoning because it brings emotion and intuition to the "logical" equation. We conclude, then, that Abduction is not only a

rational procedure but the tendency to find plausible and useful solutions that mitigate ordinary life "ignorance."

Action Research

David Coghlan

Trinity Business School, University of Dublin

Trinity College, Dublin, Ireland

Abstract

Action research is an approach to research which aims at both taking action and creating knowledge or theory about that action as the action unfolds. It starts with everyday experience and is concerned with the development of living knowledge. Its characteristics are that it generates practical knowledge in the pursuit of worthwhile purposes; it is participative and democratic as its participants work together in the present tense in defining the questions they wish to explore, the methodology for that exploration, and its application through cycles of action and reflection. In this vein they are agents of change and coresearchers in knowledge generation and not merely passive subjects as in traditional research. In this vein, action research can be understood as a social science of the possible as the collective action is focused on creating a desired future in whatever context the action research is located.

Emancipatory research · Participatory research

Introduction

As the name suggests, action research is an approach to research which aims at both taking action and creating knowledge or theory about that action as the action unfolds. It rejects the notion that research must be value free in order to be credible, in favor an explicitly socially engaged and democratic practice (Brydon-Miller et al. 2003). It embraces the notion that knowledge is socially constructed and that social science is embedded within a system of values and promotes human interaction (Coghlan et al. 2019). It has many origins and roots (Greenwood and Levin 2007; Bradbury 2015): in Aristotelian philosophy, in the social psychology of Kurt Lewin, in critical theory, in American pragmatic philosophy, and in various schools of liberation and emancipatory thought, notably Marxist and feminist and liberation theology. While the work of Lewin and the tradition of organizational change, referred to as organization development (OD), the socio-technical work of the Tavistock Institute in the UK, and the workplace democracy work in Scandinavia are the major roots for action research organizational studies (Pasmore 2001; Bradbury et al. 2008), there are important roots and strands of action research existing outside of organization and management research. The consciousness-raising work of Paulo Freire and the Marxist-based liberation movements (frequently referred to as emancipatory or participatory action research), feminist approaches to research, the return to epistemological notions of praxis, and the hermeneutic school of philosophy associated with the work of Habermas are important strands and expressions of action research which did not grow out of the post-Lewin tradition in organizations (Bradbury 2015).

Three main characteristics of action research distinguish it from other research approaches. First, action research has a dual focus: to address

a real-world issue and to contribute to theory. Second, action researchers do not merely observe something happening, they work actively at making positive changes. Third, action research is participative and democratic in nature, as research is undertaken *with* participants rather than *on* or *for* them. Susman and Evered (1978, p. 601) make the case that action research “constitutes a kind of science with a different epistemology that produces a different kind of knowledge, a knowledge that is contingent on the particular situation and which develops the capacity of members of organizations to solve their own problems.” In using the term, “scientific,” they argue, there is a need to move away from adopting frameworks from natural science in order to engage with the world of practice. As Coghlan (2016) describes, action research contributes to the realm of practical knowing as it focuses on personal, organizational, or community improvement and change and seeks to contribute knowledge that is actionable, and not merely theoretical as most research approaches do. Thus it can be understood as a social science of creating the possible. This entry provides an account of the theory and practice of action research, exploring how it focuses on pursuing worthwhile purposes in a collaborative manner.

What Is Action Research?

Action research may be defined as:

A participatory process concerned with developing practical knowing in the pursuit of worthwhile human purposes. It seeks to bring together action and reflection, theory and practice, in participation with others, in the pursuit of practical solutions to issues of pressing concern to people, and more generally the flourishing of individual persons and their communities (Bradbury 2015, p. 1).

To unpack the elements of this definition, a primary purpose of action research is to produce practical knowledge that is useful to people in the everyday conduct of their lives and their future. Accordingly, it is not about knowledge for its own sake, but knowing in the pursuit of worthwhile purposes, which may be defined in many ways from climate change, sustainable development, to

enhancing an urban or rural community, or improving an agency's service to its clients. Of course, what constitutes a worthwhile purpose and for whom is an inquiry in its own right. As action research generates practical knowledge in the pursuit of worthwhile purposes, it is participative and democratic as its participants cooperate in creating the worthwhile possible future. Participants work together in defining the questions they wish to explore, the methodology for that exploration, and its application through cycles of action and reflection. In this vein they are coresearchers and agents of change and knowledge generation and not merely passive subjects.

Action research starts with everyday experience and is concerned with the development of living knowledge. It draws on diverse forms of knowing (referred to as the extended epistemology).

- *Experiential knowing* – the knowledge arising as people encounter the realities around them
- *Presentation knowing* – the knowledge expressed in giving form to experiential knowing through language, images, music, painting, and the like
- *Propositional knowing* – the knowledge distilling experiential and presentation knowing into theories, statements, and propositions
- *Practical knowing* – the knowledge that brings the other three forms of knowing to full fruition by doing appropriate things skillfully and competently

Heron and Reason (1997) argue that practical knowing is primary as it integrates other forms of knowing. Practical knowing opens up new forms of engagement with the world (experiential knowing) and leads to representing this experience in significant patterns (presentation knowing), which in turn feeds into a revised propositional understanding of the originating questions.

An added dimension to the engagement in practical knowing as a philosophy of research is that it involves researching in the present tense (Coghlan and Shani 2017). Action research builds on the past, takes place in the present with a view to shaping the future. Accordingly, engagement in

the cycles of planning, taking action, and reflection performs both a practical and philosophical function in its attentiveness and reflexivity as to what is going on at any given moment and how that attentiveness yields purposeful action and learning. In summary, action research is a living, evolving process of coming to know rooted in everyday experience; it is a verb rather than a noun.

The Philosophies of Action Research

Action research has a solid grounding in many philosophical approaches: Aristotelian praxis, American pragmatic philosophy, Habermasian communicative action, the Lewinian social psychology of change, phenomenology, critical theory, constructivism, social constructionism, critical realism, and in the philosophy of Wittgenstein. *The SAGE Encyclopedia of Action Research* (Coghlan and Brydon-Miller 2014) provides rich introductions to action research's diverse philosophical foundations and expressions. Susman and Evered (1978) argue that the conditions from which people try to learn in everyday life are better explored through a range of philosophical viewpoints: Aristotelian praxis, hermeneutics, existentialism, pragmatism, process philosophies, and phenomenology. They proposed that action research provides a corrective to the deficiencies of standard social sciences practices by being future oriented, collaborative, agnostic, and situational implying system development and so generating theory grounded in action. The case is made that after the linguistic turn of postmodernism it is now time for the action turn in generating knowledge that is both valid and vital to the well-being of individuals, communities, and the promotion of larger-scale democratic social change.

At a glance action research seems to have a relationship with "Responsible Research and Innovation" (RRI), a term used within the European Union to denote forms of scientific research and technological development processes that take the effects and potential impacts on the environment and society into account

(Owen et al. 2013). While operating in different spheres of science, social, and physical, both are grounded in societal challenges that need to be addressed and are accountable to society and not solely to an academic discipline.

Three Practices of Action Research

As action research is a collaborative process that is undertaken in the present tense in order to achieve a worthwhile purposes, there are three sets of practices running concurrently. These are referred to as first-, second-, and third-person practice (Bradbury 2015). What is meant by these terms is that engaging in action research involves challenges of self-learning and generates subjective data in the present tense for the action researcher (first person), working with others to achieve the task which generates data in the present tense about working together (second person), and making a contribution to future action by others and to useful knowledge (third person). Traditional research has focused on creating impersonal knowledge for an impersonal readership. In a more complete vision of research as presented by action research, authentic third-person research integrates first- and second-person practices.

- *First-person practice*: As action researchers are working in the pattern of practical knowing and engaging in action research cycles with others and trying to understand and shape what is going on, they are engaging also in their own experiential learning activities, what is called first-person practice (Marshall 2016). Here, some of the core skills that action researchers need are in the areas of self-awareness and experiential learning. Keeping a learning journal is often a key tool for first-person practice.
- *Second-person practice*: Second-person practice addresses action researchers' engagement in collaborative work in co-inquiry and shared action with others on issues of mutual concern, through face-to-face dialogue, conversation, and joint decision-making and shared action and learning (Schein 2013).

- *Third-person practice*: Third-person practice is impersonal and is actualized through the contribution of the action research to an audience beyond those directly involved, such as through dissemination by reporting and publishing. Action research intentionally merges theory with practice on the grounds that actionable knowledge can result from the interplay of knowledge with action (Huxham 2003). It demands an explicit concern with theory that is generated from the conceptualization of the particular experience in ways that are intended to be meaningful to others.

Quality in Action Research

As with all approaches to rigorous inquiry, the action research paradigm requires its own quality criteria, taking quality to mean a grade of excellence. Action researchers argue that action research should *not* be judged by the criteria of traditional science, but rather within the criteria of its own terms. The characteristics of action research in the above definition by Bradbury et al. (2015) provide a set of quality criteria:

1. To what extent was the action research pursuing a worthwhile purpose?
2. To what extent has it produced practical knowledge that is useful for practitioners and robust for scholars?
3. To what extent did the action research involve all stakeholders both in the questioning and sensemaking that informed the research, and in the action?
4. To what extent did it develop over time in an evolutionary and developmental process, as individuals developed skills of inquiry and as a community of inquiry developed within a community of practice?

Settings in Which Action Research Is Practiced

Action research is practiced across a wide range of settings: business, education, nursing, health care,

community development, gender studies, and others (Bradbury 2015; Banks and Brydon-Miller 2018). Each of these setting has its own context. For instance, in the context of business and management, action research operates in the realm of strategies, practical tasks, and structured hierarchical organizational systems. Challenges to improve customer service, technology management, human resource management, supply chain management, and organizational change, for example, may occur in diverse business sectors (Shani and Coghlan 2019). In health care and nursing, action research addresses challenges of service improvement (Koshy et al. 2011; Williamson and Bellman 2012). In community development the context is largely unstructured as community organizations mobilize to engage in action to create social change (Chevalier and Buckles 2019). There is action research work being conducted to address the major contemporary global challenges: climate change, sustainability, social inequality and injustice, development, and immigration.

Action researchers are generally external to the organizations and communities with which they work, what Greenwood and Levin (2007) refer to as the “friendly outsider.” They may be academics, professional researchers, community development professionals, or organization development consultants whom a local organization, agency, NGO, or community engages to assist it with achieving the task it has identified. There is also a growing incidence of action research being done from within organizations by insiders, as when practicing managers undertake action research projects in and on their own organizations or communities (Coghlan 2019). This role is increasingly common in the context of managers participating in academic programs. In such contexts the manager takes on the role of researcher in addition to their regular organizational roles and may both manage the change project and study it at the same time.

Modalities of Action Research

One of the features of contemporary action research is that it has become a family of

approaches or modalities (Bradbury 2015). Within the theory and the practice, one finds terms like action learning, appreciative inquiry, collaborative developmental action inquiry, cooperative inquiry, learning history, and participatory action research, to name some common ones. Coghlan (2010) suggests that a way of understanding these modalities is how each modality is based on a generative insight that led to the framing of each particular modality by the person or group that first constructed it. By a generative insight he means an insight that was foundational in framing that modality and which led to the development of further insights and methods of working within each modality.

Action Learning: Action learning was articulated by Revans (1998) whose generative insight is expressed in two statements. “There can be no learning without action and no (sober and deliberate) action without learning” (p. 83) and “Those unable to change themselves cannot change what goes on around them” (p. 85). Grasping this insight is at the heart of understanding what action learning it is about, how it works, and what it seeks to achieve. Revans (1971) framed what he refers to as a *praxeology* of human action in terms of three processes:

- System *alpha*: A process of inquiry into the issue under consideration – its history, manifestation, what has prevented it from being resolved, and what has previously been attempted
- System *beta*: A rigorous exploration of the resolution of the issue through cycles of action and reflection
- System *gamma*: Individual learning through critical reflection in a group process

Appreciative Inquiry: Appreciative inquiry is built on the generative insight of inquiry as positive, that is, if people focus on what is valuable in what they do and try to work on how this may be built on, then it leverages the generative capacity to facilitate transformational action (Whitney and Trosten-Bloom 2010). This insight is itself made up of several insights: that in every organization something works somewhere, what people focus

on becomes their reality, and the language they use creates that reality. The act of asking positive questions influences people by getting them to think in new ways which may lead to acting in new ways. The appreciative inquiry cycle utilizes 4 *Ds* (*Discovery, Dream, Design, and Delivery*) to enable researchers and practitioners to move from experience to selected action and to attend to and receive insights into understand the power of positive questioning. In many respects appreciative inquiry demonstrates an explicit social science of creating the possible.

Collaborative Developmental Action Inquiry: Torbert and Associates (2004) understand collaborative developmental action inquiry as a science of action where, through insights from developmental psychology, leaders can gain insight into their own action-logics as they work to transform their organizations. From a generative insight Torbert adds the developmental dynamic of learning to inquire-in-action by emphasizing that as individuals progress through adulthood they may intentionally develop new “action-logics” through stages of ego development in how they learn to act in a timely manner.

Cooperative Inquiry: Heron and Reason (2008) define cooperative inquiry as “a form of action research in which all participants work together in an inquiry group as co-researchers and co-subjects” (p. 366). The participants research a topic through their own experience of it in order to understand their world to make sense of their life and develop new and creative ways of looking at things and to learn how to act to change things they might want to change and find out how to do things better. The generative insight for understanding cooperative inquiry is how each person is a *co-subject* in the experience phases by participating in the activities being researched and is a *coresearcher* in the reflection phases by participating in generating ideas, designing and managing the project, and drawing conclusions.

Learning History: The goal of a learning history is to increase participation in a dialogical reflection on a past action with a view to creating desired future practices (Bradbury et al. 2015). A learning history presents the experiences and understandings in the own words of those who

have gone through and/or been affected by the change in order to help the organization move forward and to contribute to our understanding of the social dynamics of organizational change. Rather than presenting the univocal voice of a single author or group of researchers, the learning history presents concurrent, multiple, and often divergent voices in an organizational story. Presenting the jointly-told tale is enabled by the format, whereby columns of narrative text are juxtaposed with interpretative voice of participants (often disagreeing) and the voice of the learning historian. The generative insight underpinning the learning history is that by presenting the history through the jointly-told tale readers may learn about organizational change. Readers of a learning history are encouraged to attend to the questions that arise from their engagement with the text as they choose which column to read first and how they might switch back and forth from participants’ narrative and learning historians’ comments, and to the insights they receive from reading multiple voices and perspectives (Gearty and Coghlan 2018).

Participatory Action Research (PAR): Participatory action research is generally understood as the form of action research that is conducted in communities, rather than in organizations. The term describes a variety of community-based approaches to knowledge generation, which combines social investigation, education, and action and emphasizes local communities in coproducing knowledge directly relevant to them for an agenda of social change (Chevalier and Buckles 2019). The generative insight underpinning this approach is that people, especially the perceived marginalized and underprivileged, can be enabled to investigate their circumstances, gain critical insight into the structures that create and maintain those circumstances, and engage in action to liberate themselves from the constrictions, if not the oppression of these structures.

There are other modalities, which are being explored in such publications as *The Sage Encyclopedia of Action Research* (Coghlan and Brydon-Miller 2014) and *The Sage Handbook of Action Research* (Bradbury 2015). It may be noted

that modalities are not mutually exclusive and some may be used together.

Action Research as the Social Science of the Possible

Social science distinguishes itself from the natural sciences in being interpretive about human experience, as it explores the meaning of how people understand themselves and their experience (Coghlan et al. 2019). Human living is mediated largely through acts of meaning (Lonergan 2005). People express themselves through language, art, symbols, rituals, how they live, and what they do. They are constantly engaging in acts of meaning in their experiencing, their understanding, their judgments, their decisions, and their actions. Meaning is not only what is experienced but is also what is questioned, understood, interpreted, and affirmed. There is also the meaning they create by intending, investigating possibilities, planning, weighing options, making contacts, taking action, and learning. Meanings are shared in communities and organizations which come about because people share common meanings from common fields of experience, common understandings, common measures of judgment, and common consent.

Human living can be understood only in terms of meanings, such as purpose and value, terms that do not apply to knowledge of the physical world. As action research begins with everyday experience and is concerned with the development of living knowledge, it seeks to generate practical knowledge in the pursuit of worthwhile purposes. Its participative and democratic values' base acts as the foundation of how its participants work together in the present tense in defining the issues they wish to address, the questions they wish to explore, the methodology for that exploration, and its application through collaborative cycles of action and reflection. Action research is emancipatory; it leads not merely to a new situation and to new practical knowledge, but also to new abilities to create knowledge. In this vein it can be understood as a social science of the possible as the collective action is focused on creating

a desired future in whatever context the action research is located.

Summary

This entry has presented action research as a social science of the possible. Action research is emancipatory as an approach to research that does not distinguish between research and action; it addresses the theme of research in action in the pursuit of worthwhile purposes. It leads not merely to new practical knowledge, but to new abilities to create knowledge.

Adjacent Possible

Lennart Björneborn

Department of Communication, University of Copenhagen, Copenhagen, Denmark

Abstract

Adjacent, i.e., nearby, possibilities constantly emerge in a multitude of settings for a multitude of entities. When these possibilities are explored, yet new possibilities emerge. The concept of the “adjacent possible” was introduced by Stuart Kauffman (1996; 2000) in evolutionary biology and complex adaptive systems to explain how biological evolution can be seen as exploration and actualization of what is adjacent possible, i.e., available at hand. The concept has now disseminated into a wide range of research fields including economy, innovation studies, technological evolution, cultural evolution, learning processes, recommender systems, and design studies.

The “adjacent possible” can be defined as “the set of possibilities available to individuals, communities, institutions, organisms, productive processes, etc., at a given point in time during their evolution” (Loreto 2015, p. 9). The concept of the “adjacent possible” is useful for understanding how new possibilities emerge, and how they are constrained, discovered, explored, actualized, developed, reconfigured, designed, and so on, in an interplay between what is actual and what is possible for specific entities in specific settings.

In this entry, the history and the state of art of research on the “adjacent possible” is briefly outlined. Discussion focuses on four essential aspects of “adjacent possibles”: (1) topologies

of “adjacent possibles,” (2) types of “adjacent possibles,” (3) serendipity as actualization of “adjacent possibles,” and (4) designing for “adjacent possibles.”

Keywords

Adjacent possible · Affordance · Enablement · Evolution · Actualization · Possibility spaces · Topology · Diversity · Serendipity · Design

Introduction

The world is full of possibilities, and new possibilities constantly emerge in a multitude of settings. Possibilities emerge on individual and collective levels, from micro to macro settings. When possibilities are explored, yet new possibilities emerge.

New possibilities are part of human everyday lives. As stated by Loreto et al. (2016), we “constantly adopt new technologies, conceive new ideas, meet new people, and experiment with new situations” (p. 59).

We live surrounded by possibilities we can discover, explore (or ignore), interact with, and make use of, depending on our capabilities, experiences, and interests.

However, not all things are available and possible in all situations. This is an important aspect of the so-called “adjacent possible.” Thus, there are **limits** to what are adjacent, i.e., nearby, possibilities in specific situations in specific environments for specific entities/agents, depending on **affordances**, i.e., capacities, usage potentials, of the specific environments (► [Affordance](#)).

In evolutionary biology and complex adaptive systems, the concept of the “adjacent possible” was introduced by Stuart Kauffman (1996, 2000) to explain how “**biospheres**, on average, may enter their adjacent possible as rapidly as they can sustain” (Kauffman 2000, p. 22). This means, **evolution** can be seen as an exploration of the adjacent possible, or as expressed by Kauffman (2017), “life literally creates the opportunities into which it then becomes.”

As will be further outlined below, the concept has now disseminated into a wide range of research fields including economy, innovation studies, technological evolution, cultural evolution, evolution of language, conversation analysis, learning processes, recommender systems, and design studies.

The “adjacent possible,” cf. Fig. 1, can be defined as “the set of possibilities available to individuals, communities, institutions, organisms, productive processes, etc., at a given point in time during their evolution” (Loreto 2015, p. 9). There is a rich variety of entities each with their own sets of adjacent possibilities. This variety is accentuated by another definition of the “adjacent possible” as “the set of things – could be molecules, organisms, technological products, ideas, etc. – that are one step away from what actually exists and that could be reached by the **incremental recombination** of the existing elements” (Gravino et al. 2019, p. 2).

An example of the “adjacent possible” could be how new **technologies** emerge and evolve at specific points in time when specific technological, organizational, cultural, societal, etc., preconditions are at hand to enable the next

Adjacent Possible,

Fig. 1 Illustration of the “adjacent possible” in a graph that conditionally expands from situation (a) to situation (b) when the white node in (a) is visited for the first time (Loreto et al. 2016)

“adjacent possible” steps. The **World Wide Web**, WWW, was **invented** in 1990 – as an “adjacent possible” technology at that time – by combining newly available technologies, like the Internet, hypertext, SGML markup language, and personal computers (Invention, Possible in Technology).

When adjacent possibilities emerge and are actualized, that is, are unfolded and made use of, like in the WWW example above, new possibilities do not come alone. Instead, they come with “an entourage of surrounding possibilities, a cloud of other potentially new ideas or experiences that are thematically adjacent to it and hence can be triggered by it” (Tria et al. 2014, p. 1). Possibilities often unfold exponentially with **bursts** of new possibilities enabling yet new possibilities, as can be seen, e.g., in the last 30 years of immense media development on the Web.

The concept of the “adjacent possible” is useful for understanding how new adjacent possibilities emerge, and how they are constrained, ignored, discovered, explored, actualized, developed, disseminated, reconfigured, designed, and so on, in an interplay between what is actual and what is possible for specific entities in specific settings at specific points in time.

Steven Johnson (2010) presented the concept of the “adjacent possible” for a bigger audience – also in academia – with his book *Where Good Ideas Come From: The Natural History of Innovation* (► [Innovation](#)). According to Johnson, “the adjacent possible is a kind of shadow future, hovering on the edges of the present state of things, a map of all the ways in which the present can reinvent itself” (p. 31). Johnson underlines how the boundaries of the “adjacent possible” grow as they are explored: “Think of it as a house that magically expands with each door you open” (p. 31).

Every adjacent possible thing that we actualize – like visiting a new node in Fig. 1, or opening a door into a new available room in Johnson’s expanding house of possibilities – enables discovery of, and accessibility to, yet new possibilities we can choose to actualize. In this way, the adjacent possible emerges when explored.

In the rest of this entry, the adjacent possible will be written without quotation marks. The plural form, adjacent possibles, will be used in line with terminology by, e.g., Kauffman (2014) and Cambray (2019).

In the following section, the history and the state of art of research on the adjacent possible will be briefly outlined. The subsequent discussion focuses on four essential aspects of adjacent possibles: (1) topologies of adjacent possibles, (2) types of adjacent possibles, (3) serendipity as actualization of adjacent possibles, and (4) designing for adjacent possibles.

History and State of the Art

Stuart Kauffman (1996) introduced the concept of “the adjacent possible” in a working paper on “the nature of autonomous agents and the worlds they mutually create” in **evolutionary biology** and **complex adaptive systems**. The working paper was transformed into a book in which Kauffman (2000) outlines the new concept in relation to how “autonomous agents forever push their way into novelty – molecular, morphological, behavioral, organizational” (p. 22). Kauffman formalizes this push into **novelty** as “the mathematical concept of an ‘adjacent possible’” (ibid.) (► [Novelty](#)).

Kauffman (in Brockman 2003) discusses how **biospheres** on average keep expanding into the adjacent possible. By doing so, they “increase the **diversity** of what can happen next,” and thus, they may “maximize the rate of exploration of the adjacent possible” (ibid.). According to Kauffman (2017) this means, “[d]iversity begets more diversity” (Diversity).

Evolution as an exploration into the adjacent possible, means the biosphere is envisioned as “incrementally expanding in stepwise fashion” (Cambray 2019, p. 63). Cambray further notes that, when abstracted, this approach is “of more general utility in examining how **complexity** evolves in our universe from various points of origin (e.g., the big bang; the formation and clustering of galaxies, stars, planets; life; mind; civilization and so on)” (ibid.) (► [Complexity](#)).

A key feature of the topological structures of adjacent possible spaces is that they are constantly restructured and **reconfigured** when novelties appear. Gravino et al. (2019, p. 8) state how “the adjacent possible space is dynamically reshaped while it is explored” and Hochberg et al. (2017, p. 9) note the “**recombinatory** shuffling” in connection with how “**novelty** and **innovation** alter spaces and generate new spaces.”

The key feature of “**reconfigurability**” of adjacent possible spaces is strongly interweaved with another key feature: “**unprestatability**” (Longo et al. 2012). It is not possible to prestate, i.e., **predict**, the evolution of all adjacent possibilities (Prediction). In other words, the **topology** of adjacent possible spaces is not predictable but “unprestatable” (Kauffman 2000), as it is constantly reconfigured, i.e., reshaped and restructured by new possibilities that are explored and actualized. Kauffman thus argues against the predictability of evolution, and states, “we cannot mathematize the detailed becoming of the biosphere” (Kauffman 2014, p. 3).

Instead of “entailing laws” determining the evolution of the biosphere, Kauffman (2014, p. 4) points to “**enablement**” as an evolutionary driving force. He outlines an explanatory framework for how “Actuals” emerge in evolution and constitute new “**boundary conditions** that are **enabling constraints**” (p. 3) for new adjacent possibles enabling yet new actualizations enabling yet new adjacent possibles. This means, evolution “flows into a typically unprestatable succession of adjacent possibles” (p. 3).

In a similar vein, McCaffrey and Spector (2018) use the concept of the adjacent possible in relation to so-called “**nonenumerability**,” meaning the set of possible interactions that an object can participate in is not computably enumerable (p. 3). This is line with Kauffman (2019, p. 135) who exemplifies, “we find new uses of screwdrivers all the time. But these new uses are typically unprestatable.”

In this context, Kauffman (2000) discusses so-called “**dimensionality**” as the “number of types of events that can happen next” (p. 22). The topological space of possibilities has a “dimensionality” that is “unprestatable” as we

“cannot measure the ‘size’ of the Adjacent Possible” (Kauffman (2019, p. 135). Stressing this “unprestatable, **open-ended becoming**” (Kauffman 2017), “not only do we not know what will happen, we do not even know what can happen” (ibid.).

In his book *A World Beyond Physics: The Emergence and Evolution of Life*, Kauffman (2019) discusses the adjacent possible and draws parallels between the **biosphere** and the global **economy**. Just like new species in the biosphere create niches for further new species, according to Kauffman, new goods in economy “create niches for yet further new goods and services and production capacities” (p. 137) (Economy).

The concept of the adjacent possible has now disseminated into a wide range of research fields, including **economy** (Kauffman 2019), **innovation studies** (Hochberg et al. 2017; McCaffrey and Spector 2018), **technological evolution** (Tria et al. 2014), **cultural evolution** (Gravino et al. 2016), **evolution of language** (Ferrer-i-Cancho 2016), **biosemiotics** (Favareau 2015), **artistic emergence** (Hoelscher 2014), **design studies** (Ruttonsha 2017), **recommender systems** (Gravino et al. 2019), **learning processes** (Jörg 2017), **conversation analysis** (Favareau 2015), and **psychotherapy** (Cambray 2019). Some of these studies have already been mentioned. Some of the others will briefly be outlined here.

Substantial research on the adjacent possible has been done by the *Kreyon* project, 2014–2017, based at the Institute for Complex Systems at the Sapienza University of Rome. They have investigated the “dynamics of novelties correlated via the adjacent possible” (Loreto et al. 2016), seeing it as “a fundamental factor in the evolution of human societies, biological systems and technology” (Loreto 2015, p. 1). The project has developed **mathematical models** for the adjacent possible in processes of **creativity** and **innovation** “both at the individual and collective level” (p. 7).

In several papers, researchers in the *Kreyon* project have published results from their empirical investigations and mathematical modelling of the adjacent possible (e.g., Tria et al. 2014; Loreto

2015; Loreto et al. 2016; Gravino et al. 2016; Monechi et al. 2017; Tria et al. 2018; Gravino et al. 2019).

Key notions in the Kreyon project were “innovation” and “novelty” (Innovation, Novelty). **Innovation** here meaning “something created for the first time, something new to the world, something never seen before” (Tria et al. 2014, p. 1). By contrast, a **novelty** is “merely anything that is new to you (or to someone else)” (ibid.). The researchers investigated the “dynamics of **correlated novelties**” (ibid.), i.e., how novelties enable yet new novelties. A mathematical model was tested on four data sets of novelties in different **cultural systems**: edits in Wikipedia, tags in annotation systems, word sequences in texts, and finding new songs in online music catalogues. Results showed similar patterns between how novelties emerge in everyday life and how innovations emerge from the adjacent possible.

As noted by Gravino et al. (2016, p. 115), “[e]ach new outcome of a cultural system is influenced by prior outcomes,” e.g., edits in Wikipedia that add to previous edits. This is related to notions of “**cumulative cultural evolution**” and “**cumulative technological evolution**” (Mesoudi et al. 2013), and in line with Johnson (2010, p. 33) stating, “[t]he history of life and human culture, then, can be told as the story of a gradual but relentless probing of the adjacent possible, each new innovation opening up new paths to explore.”

Researchers in the Kreyon project also empirically investigated other cultural systems like the IMDb Internet Movie Database as a “movie influence network” (Gravino et al. 2016, p. 116) with network nodes as movies and connections showing what movies have “influenced (e.g. homage, mentions, spoofs, etc.) subsequent movies” (ibid.). Monechi et al. (2017) looked into the creation of Twitter hashtags, the evolution of online code repositories like GitHub Archive, the creation of texts in Wikipedia and Gutenberg Corpus, and the listening of songs on Last.fm. In a discussion of this research, Cambray (2019) points to how findings in the Kreyon project “hint at a general model of the flow of **innovation** in

culture which might be explored through a network of the possible” (p. 64).

In relation to the adjacent possible, Monechi et al. (2017) discuss the important “two contrasting forces” when we interact with different environments: “the drive to explore the adjacent possible and the need to exploit the already known” (i.e., the actual) (p. 3). This means, finding a balance between “explore” and “exploit” becomes crucial.

In subsequent studies, researchers from the Kreyon project have looked also into **recommender systems** as platforms for presenting novel possibilities, e.g., in music recommendation. Gravino et al. (2019) discuss “novelty-driven recommender systems,” and find that the “interplay between the mechanism of **learning** and the restructuring of the adjacent possible space” seems to be very promising ingredients for the next generation of recommender systems (p. 9). Learning while exploring adjacent possibilities in recommender systems can help users gradually become more familiar with specific contents in a way that “progressively dislodges us from our **comfort zone**, but without pushing us too far” (p. 1).

Learning processes are also addressed by Jörg (2017) who uses the concept of the adjacent possible in relation to the Soviet psychologist Vygotsky’s concept of the “**zone of proximal development**” (ZPD) (► [Zone of Proximal Development](#)). ZPD deals with what next a person can learn with the help of others (► [Possible in Education](#)). Jörg underlines how Vygotsky’s “focus was not only process-oriented, but also very much possibility-oriented” (p. 30). In a similar vein, Cambray (2019) discusses adjacent possible developments of understandings, interpretations, and processes in **psychotherapy** sessions.

Hoelscher (2014) addresses “the adjacent possible and **artistic emergence**” in a proposed model for **artistic evolution** and change. Applied to art, “breakthroughs in the adjacent possible prompt the crystallization and dispersion of new styles and discourses” (p. 2).

Ruttonsha (2017) draws on the concept of the adjacent possible in relation to **design thinking** and “nuances of *what is*, *what could be* and *what*

should be” (p. 7). In this context, she points to the notion of “**design space**” defined as the “total set of prospective designs that could be rendered” (p. 17) (► [Possible in Design](#)).

The last research example here is a **semiotic** approach to the adjacent possible by Favareau (2015) examining “the creation of the relevant next” and how “living systems capture the power of the adjacent possible through sign use” (► [Semiotics](#)). Favareau sees the adjacent possible as an “**organizing principle** in nature” that shares much in common with the American philosopher **Charles S. Peirce**’s understanding of “a world of ongoing possibility [...] sculpted into its present state by its history of prior actualizations upon that possibility” (p. 591). Finally, in the context of **conversation analysis**, Favareau also recognizes the principles of the adjacent possible in “the moment to moment unfolding of **everyday communication**” (p. 590).

Discussion

The following discussion on the adjacent possible and relations to possibility studies deals with four essential aspects of the concept alluded to in the previous sections: (1) topologies of adjacent possibles, (2) types of adjacent possibles, (3) serendipity as actualization of adjacent possibles, and (4) designing for adjacent possibles.

Topologies of Adjacent Possibles

Topology can be defined as “the mathematics of context, connectivity and consistency” (Shields 2013, p. 104). In topology, shapes and spaces are studied with focus on how surfaces, volumes, boundaries, folds, holes, etc., interconnect with each other.

As earlier noted, the adjacent possible can be conceived as a space of nearby, available possibilities. This abstract space can be seen as a **topology of possibilities**, as a complex and dynamic network of interconnected and **interdependent possibilities**. An interesting question here is “how close or far the possible is from the actual” (Glăveanu 2018, p. 521). The concept of the “adjacent possible” deals with this

very question by focusing on close, nearby possibilities.

Topological approaches are present in several studies of the adjacent possible. For example, Loreto et al. (2016) view **evolution** as “a path in a complex space, physical, conceptual, biological, technological, whose structure and **topology** get continuously reshaped and expanded by the occurrence of the new” (p. 59), cf. Fig. 1. This is in line with Johnson (2010, p. 32) stating, “one way to think about the path of evolution is as a continual exploration of the adjacent possible.”

Topologies may enable movement for agents exploring along structural edges and connections. However, topologies also can limit and **constrain** movement, as not all parts of a topological structure may be easily reachable. Some parts are first reachable and encounterable when other steps have been taken. As noted by Hochberg et al. (2017, p. 9), “topological constraints exist and, as such, **innovation** is not (entirely) open-ended.”

Reachability across a network deals with how to reach from one node to another along intermediate paths. Such topological “**reachability structures**” (Björneborn 2006) also have to do with what is adjacent possible. “The adjacent possible holds what is potentially in reach” (Cambray 2019, p. 64).

Closely related to reachability structures are so-called “**small-world**” **network** aspects (Björneborn 2006). Small-world networks, like brains, social media, and many other complex, dynamic networks, are characterized by high clustering (short *local* distances) of network entities, in combination with shortcuts (short *global* distances) connecting otherwise distant entities. Small-world topologies provide short distances between, e.g., associative ideas in our brain, people on social media, or research papers in citation networks (ibid.). In this way, small-world aspects in topologies of possibilities may enable adjacent possible encounters to unfold.

When an agent explores the topology of possibilities accessible for this agent in a specific setting, cf. Fig. 1, new parts of the topology may turn up in the shape of new possibilities that could not be predicted (Prediction). As outlined before,

this **unpredictability** – this **unprestatability** – affecting **uncertainty** in human life (► **Uncertainty**) – of what is adjacent possible in a specific setting is a key feature of the topology of adjacent possible spaces.

However, the notion of the “adjacent possible” may invite prediction, trying to estimate what is adjacent and thus available, as can be seen in the previously mentioned *Kreyon* project in their mathematical modelling, e.g., in recommender systems. Nonetheless, as noted earlier, there is still an unpredictability/unprestatability that is strongly interweaved with how the topology of possibilities is constantly restructured and reconfigured as new possibilities are explored and actualized.

In this context, it is interesting to look at research in **temporal logic** including **branching time structures** in topologies of time. The first systematic discussion of branching time was presented in Prior (1967) and since elaborated in many scientific contributions. A recent important contribution is Rumberg (2019), who discusses “forking paths” in “**trees of possibilites**” (p. 145) with branches representing temporal alternatives and possibilities for the future.

In research on **creativity**, the topological notion of “**possibility spaces**” is used in a similar way as in research on the adjacent possible (► **Creativity**). “The work of any creative system can be viewed as a process of search through a space of possibilities or a ‘possibility space’” (Perkins 1995, p. 496).

In sociology exists the comparable topological concept of “**opportunity structures**” (Merton 1995). The concept points to “social distributions of resources” (Crothers 2004, p. 31). “Because it can be pushed and pulled by various social actors the ‘opportunity structure’ itself can change over time, often then altering the possibilities different people have for accessing resources” (ibid.). This **reconfigurability** of opportunity structures complies with the concept of the adjacent possible. Merton and Barber (2004) apply the concept of “opportunity structures” in relation to **serendipity**, noting, “microenvironments do differ in their opportunity structures for such serendipitous discoveries” (p. 297) (► **Serendipity**).

Possibility spaces and opportunity structures can be seen as adjacent possible layers of folds within folds, like crumpled paper (Björneborn 2006). Such “crumpled-up” **small-world** topologies enable adjacent possible encounters across dissimilar entities, also enabling **serendipity** as will be elaborated further below.

We often prefer and depend on paths we have used before. “As we go about our lives, in fact, we silently move along physical, conceptual, biological or technological spaces, mostly retracing well-worn paths, but every so often stepping somewhere new, and in the process, breaking through to a new piece of the space” (Tria et al. 2014, p. 6). In this context, so-called “**path dependency**” describes how “the set of decisions one faces currently are limited by the decisions one has made in the past, even though past circumstances may no longer be relevant.”¹ Exploiting existing paths may thus be easier than exploring new paths. This means, the present is “never a clean slate where we are free to make any decision,” instead history matters and the present is “**contingent** on how we got to this point” (ibid.). Path dependency is linked with the “exploit” element of the earlier mentioned “two contrasting forces” (Monechi et al. 2017) dealing with the tension between exploiting already actualized paths and exploring new possible paths. Hence, path dependency may **limit** what we perceive as adjacent possible and whether we find something potentially interesting by **serendipity**, as will be discussed further below.

Types of Adjacent Possibles

As alluded to in the introduction, the adjacent possible can be seen as **affordances**, i.e., “action possibilities” (Norman 1999) or “usage potentials” (Björneborn 2017), as relations between environmental and individual factors (► **Affordance**). In other words, the adjacent possible can be seen as capacities of an environment that can be met, actualized, by capabilities of agents in this environment.

¹ <https://systemsacademy.io/glossary/path-dependency/>

In the affordance approach to the adjacent possible, what is “adjacent” and what is “possible” depend on both external/environmental and internal/individual factors, meaning there are different **types** and **modalities** of adjacent possibles. Thus, something can be adjacent possible on different **parameters** and **levels**, e.g., individually, cognitively, collaboratively, socially, culturally, legally, politically, economically, technically, digitally, physically, and so on.

As implied above and stressed in the introduction, not all things are available and possible in all situations. Similar to the adjacent possible, an important aspect of affordances is the **constraints** they inflict upon agents in a specific setting (Norman 1999). These **limits of possibility** mean that not anything is possibly realizable and actualizable for agents with specific capabilities in settings with specific affordances.

A key aspect of the notion of the adjacent possible is precisely that it “captures both the **limits** and the **creative potential** of change and innovation” (Schoen et al. 2012, p. 3). In a similar vein, Testa (2009, p. 995) notes that the adjacent possible “sets limits to the accessible space.”

As earlier mentioned, something can be adjacent possible on a **collective** macro level as well as on an **individual** micro level. Monechi et al. (2017) consider “agents each exploring independently her own space of possibilities” (p. 10). When actualizing the adjacent possible on an individual level, what is “actual,” “adjacent,” and “possible,” respectively, is seen from each individual’s perspective, including individual experiences, abilities, and interests. What is actualized by one person may still only be adjacent possible but non-actualized for another person, or not available and “far-away” possible for yet others.

An example of disparate adjacent possibilities due to disparate individual capabilities can be found in the **fairy tale** of *Jack the Dullard* (or: *Clumsy Hans*) by Hans Christian Andersen. Jack the Dullard, the youngest brother of three, discovered adjacent possible resources – a dead crow, an old wooden shoe, and some wet clay – not noticed by his two brothers riding in advance

on the same route to the castle. Creatively actualizing, combining, and reconfiguring these adjacent possible resources helped Jack the Dullard to impress the princess to marry him.

On both individual and collective levels something can be internally and externally adjacent possible, including on the different parameters listed above: physically, digitally, economically, politically, etc.

Adjacent possibles can be accessible through **affordances** and **modalities** that are **physical/analogue** or **digital** (Modalities). Flows of people, interests, resources, and affordances may intersect in analogue and digital ways, actualizing what is adjacent possible. However, our physical **bodies** with their sensory-motor systems can actualize and experience adjacent possibles in physical environments not possible in digital ones. Conversely, digital environments, like hypertext structures on the **Web**, can give quicker access to information and contacts, than is possible in the physical world. Thus, physical and digital **access points** to adjacent possibles can supplement each other.

Finally, adjacent possibles can be actualized in both **convergent**, goal-directed, ways, and in **divergent**, exploratory, serendipitous ways, using terminology from Björneborn (2017) (► **Divergent Thinking**). For example, in **urban spaces**, **museums**, and **libraries**, we can find adjacent possible resources in both convergent and divergent ways, as enabled by **architecture** and **design** of those settings. This will be elaborated further below.

Serendipity as Actualization of Adjacent Possibles

“Engaging with the possible is a distinctively human way of living,” as stated on the webpage for the present Encyclopedia². Correspondingly, Glăveanu (2018, p. 519) talks about “engaging with the possible in the sense of both becoming aware of it and actively exploring it.” **Serendipity** deals with exactly this; “engaging with the

²<https://meteor.springer.com/possible>

possible,” in the sense of both becoming aware of possibilities and exploring them.

The concept of the adjacent possible can be used to understand how we serendipitously discover, explore, and learn from new “neighboring” things in all fields of life. Serendipity is an **actualization** of adjacent possible resources we find interesting but have not planned beforehand (► [Serendipity](#)). More precisely, serendipity happens when we in unplanned ways, as perceived from our individual perspectives, encounter resources (information, things, people, etc.) – as adjacent possibles – that we find interesting (Björneborn 2017).

Adjacent possible resources that may trigger serendipity come in the shape of ideas, information, people, objects, technologies, events, and countless other things that can provide **novelty** for specific individuals in specific settings (Imagination, Improvisation, Inspiration). For example, serendipity often plays an important role in disruptive **innovations** and **scientific discoveries** (Merton and Barber 2004). Serendipity also happens in **everyday life**, e.g., when we follow our **curiosity**, find new interesting information on social media, or stumble upon interesting people we had not planned to meet (► [Curiosity](#)). In this way, adjacent possible serendipity may open doors to new directions in our lives and influence **life courses** as we discover, explore, and actualize **life opportunities** (Life Course, Life Creativity, Possible in Human Development).

Serendipity transcends what is actual by exploring and exploiting possibilities. In the context of actuals and potentials, serendipity can be seen as a **contingency**, as something *not* inevitable, yet *not* impossible. In other words, serendipity is characterized by a contingent absence of **impossibility**.

Relating to previous discussions, serendipity deals with opening **topologies** of possibilities. Topologies of possibilities we can discover, explore, and actualize. We live and move in cognitive, social, physical, and digital landscapes full of adjacent possible serendipity. This means that at every moment on our paths in life, we are surrounded by adjacent possible opportunities

for serendipity. Opportunities we may discover or overlook.

The American journalist Max Lerner (1902–1992) wrote, “I am neither an optimist nor pessimist, but a **possibilist**.”³ In *Finnegan’s Wake*, the Irish author James Joyce (1882–1941) coined the word “**serendipitist**” (Merton and Barber 2004, p. 260). One may say “serendipitists” are “possibilists” making use of opportunities to be met in all kinds of situations. **Possibility-oriented** people may thus be **serendipity-prone**, as “serendipitists” use their “**sense of possibility**” (“Möglichkeitssinn”) as the Austrian author Robert Musil (1880–1942) called it in his book *The Man Without Qualities*.

Serendipity can be interest-driven, and **interest development** can be serendipity-driven. How **interests** emerge and evolve over time, e.g., for researchers or in everyday life, is affected by serendipitous encounters with adjacent possible people, objects, information, etc. When we actualize adjacent possibles, we pay interest to them, make use of them, and let them into our existence and interests.

In the context of **everyday life**, the notion of “**micro-serendipity**” (Bogers & Björneborn 2013) is relevant. Micro-serendipity deals with serendipitous experiences in micro settings of everyday life, like when we see fellow train commuters read something that triggers our **curiosity** and interests. Thus, micro-serendipity is about actualizing everyday adjacent possible “**little novelties**” (Tria et al. 2014; Loreto 2015).

Micro-serendipity inviting into adjacent possible walks in life could happen when we explore new cities by improvising walking routes not planned in detail beforehand. This may enable us spontaneously to find interesting objects, shops, buildings, people, etc. Each adjacent possible finding can change directions of the walk. Such an urban walk is an example of an adjacent possible **event chain**, with adjacent possibles leading to new adjacent possibles. One could here talk about “micro adjacencies”; small situations and

³ <https://www.nytimes.com/1992/06/06/arts/max-lerner-writer-89-is-dead-humanist-on-political-barricades.html>

events as **fractals** of adjacent possibles; as adjacent possibles *within* other adjacent possibles. Such “micro adjacencies” are constantly actualized through micro-serendipity in everyday life and could be related to **everyday creativity**, so-called “**little c**” **creativity** (Craft 2015).

As evident in previous sections, **innovation** and **creativity** are closely related to the adjacent possible (Innovation, Creativity, Creative Development). For instance, Loreto (2015) talks about “specific pathways through which creativity can emerge: e. g., recombination, exaptation, tinkering, serendipity, trial and error” (p. 2). The referred “**exaptation**” is a concept from evolutionary biology about reconfiguring and repurposing what is already available (Andriani 2017). For example, feathers had other functions in **evolution** before they were “exapted” in adjacent possible ways in the evolution of flying animals. The earlier mentioned example from the evolution of technology with the **invention** of WWW was about combining existing (known) technologies in novel (yet-to-be-known) ways, in a kind of exaptation (► **Invention**).

Serendipity is a close sibling to creativity and innovation. Serendipity, creativity, and innovation emerge at edges of the adjacent possible. These creative practices happen at edges of what we already know, i.e., is “actual” to us – when something we do not yet know becomes adjacent possible to us, i.e., literally becomes within our reach and triggers our curiosity and interests.

Serendipity is clearly related to **learning/scaffolding** processes (Education), as we only understand something new (yet-to-be-known) in relation to something we already understand (know). This means, new details to be learned must connect – in adjacent possible ways – to already known details. Learning – and serendipity – depends on previous knowledge. “Chance favors the prepared mind,” as stated by Pasteur (Merton and Barber 2004, p. 259).

Serendipity may help us open doors into what is adjacent possible for us. As *all* adjacent possible resources in life never can be noticed, nor predicted, cf. the earlier mentioned “**unprestatability**,” our ability for serendipity is important for discovering and actualizing what is potentially interesting for us. Hence, serendipity

plays a fundamental role in how we discover, explore, and learn new things – i.e., things that are adjacent possible – in all fields of life (Björneborn 2017).

Sheer **combinatorics** makes serendipity commonplace (► **Probabilistic Thinking**). As earlier noted, the world is constantly full of new adjacent possibles combinable and reconfigurable in innumerable and unprestatable ways. This unprestatable “**dimensionality**” of adjacent possibles – including the rich **diversity** of everyday “micro adjacencies” addressed above – explains why serendipity is a commonplace phenomenon (Diversity).

Designing for Adjacent Possibles

Where serendipity *grasps* possibilities, **design** *creates* possibilities. In continuation of previous discussions on topologies and types of adjacent possibles, including serendipity, it is interesting to look at how we can design for adjacent possibles (Possible in Design, Design Thinking). More specifically, how we can design **physical** and **digital** environments to function as individual and collective “**possibility spaces**,” so we more easily, serendipitously, and playfully can discover, explore, and actualize potentially interesting “adjacent” resources. That is, designing “possibility spaces” where our **interests** can be triggered, challenged, and developed.

How can we design for something that cannot be predicted? Of course, designing “possibility spaces” gives no guarantee for specific possibilities to be discovered and actualized. However, design can *enable* discoveries and actualizations.

According to Johnson (2010), “**innovative environments** are better at helping their inhabitants explore the adjacent possible” (p. 41). Björneborn’s (2017) framework on affordances for **serendipity** may be used to design environments that enable discovery and exploration of adjacent possibles (► **Affordance**). According to this framework, there are three key **affordances** for facilitating serendipity: *diversifiability*, *traversability*, and *sensoriability*, covering capacities of physical and digital environments to be diversified, traversed, and sensed. Designing for adjacent possibles may take into account these three key affordances. First,

the degree of *diversifiability*, i.e., how many different adjacent possibles there are in a given environment and how easily reconfigurable, i.e., easily diversifiable, is this environment? Second, the degree of *traversability*, i.e., how easy is it to access and navigate among adjacent possibles in a given environment? Third, the degree of *sensoriability*, i.e., how easy is it to discover and perceive adjacent possibles in a given environment?

Urban spaces, museums, and libraries are examples of designed environments that often have rich diversifiability, traversability, and sensoriability (Björneborn 2017). This means they are good possibility spaces for discovering and accessing adjacent possible resources like information, objects, people, etc. (Possible in Architecture). Urban spaces, museums, and libraries contain a multitude of adjacent possible resources waiting to be actualized by a multitude of people with a multitude of **interests** (Pluralism). As earlier noted, urban spaces, museums, and libraries also can help people to find and choose adjacent possible resources in both **convergent**, goal-directed ways, e.g., through signage, and **divergent**, exploratory ways, e.g., through serendipity and **play** (► [Play](#)). Design of digital recommender systems, addressed earlier, may profit from such combinations of convergent and divergent approaches, including the key affordances above and design elements that help users prioritize among discovered adjacent possibles.

Concluding Summary

Summing up, adjacent possibles are actual possibilities. They literally constitute what actually is possible for a specific entity with specific capabilities in a specific setting at a specific time. In contrast to more “far-away” and less accessible possibilities, adjacent possibles thus are possibilities that are available and ready-at-hand for a specific entity.

As outlined, the concept of “the adjacent possible” has found its way into a wide range of research fields, in particular during the last decade.

In the context of the present Encyclopedia, “the adjacent possible” can be seen as a key concept for a better understanding and awareness of manifold aspects in possibility studies that have been outlined in this entry:

- A better understanding of the **topologies** of actualizable but unprestatable possibilities constantly and dynamically emerging, evolving, and reconfiguring around us as adjacent possible resources.
- A better understanding of the **limits** of possibility; not anything is possibly actualizable for agents with specific capabilities in settings with specific **affordances**, i.e., capacities.
- A better understanding of different **types, levels, and modalities** of adjacent possibles: individually, collectively, physically, digitally, convergently, divergently, etc.
- A better understanding of **serendipity** as **actualization** of adjacent possibles when we discover, explore, and learn from encountering new adjacent possible resources in all fields of life.
- A better understanding of how we can **design** physical and digital environments to function as **possibility spaces** that can support us in discovering, exploring, and choosing adjacent possibles that can be actualized through curiosity, serendipity, creativity, play, interest development, etc.

Additionally, the concept of the “adjacent possible” *itself* might trigger new adjacent possible thinking and research development – like opening new doors to new rooms in Johnson’s aforementioned analogy of an expanding house of possibilities.

²Federal University of Pernambuco, Recife, Brazil

Abstract

Adoption is a noun form of the verb *adopt*, which comes from the Latin verb *adoptāre*, meaning “to choose for oneself.” We chose to define adoption as a way of becoming a parent and, more specifically, the so-called legal adoption. However, over time and in communities that are more isolated from the dominant collective culture, as in so-called traditional communities (e.g., indigenous, African-based, etc.), spontaneous adoptions occur, guided by community cultural practices, without any state intervention, and this phenomenon can be designated as the circulation of children, in which neighbors, relatives, and, at times, the entire community take care of that child or children in general. It is important to point out that all the ways of conceiving adoption depend on the dominant perspectives both on the child's place in society and on the relationship of adults to them. Thus, we emphasize that this concept is changeable over time and in emerging contexts. Legal adoption designates a way of becoming parents that is available for that purpose and under

the responsibility of the state. Adoption is a way of forming a family that is increasingly on the rise, having gained visibility in several countries in recent decades. Children and adolescents eligible for adoption are always victims of abandonment, neglect, psychological and physical abuse, and even wars or natural disasters. This modality of family construction is crossed by sociocultural and psychological aspects, both for the adoptees and the adopters. Legal adoption requires adopters not only show affection but compliance with the legal procedures required in each nation. In the broad sense, adoption defines the spontaneous acceptance of people, animals, social causes, etc., which can lead a person to always act in defense, or militancy, of what was adopted by him. We will address adoption to the studies of the possible as an alternative resulting from the dialogue established between the dominant and nondominant perspectives, in the context of building parenting.

Introduction

People's life trajectories may have more or less expected phases. In adulthood, one of these phases is the experience of becoming a father and mother, regardless of sexual orientation or gender identity. But trajectories do not develop linearly. On the contrary, they are marked by disruptive events (Zittoun 2012) and this includes the impossibility of biologically generating the desired children, causing some people to consider others possibilities to get pregnant and give birth to a child. Sometimes, facing infertility, some people start considering adoption (Valério 2013) as one of the possibilities.

Mothering/fathering differs from motherhood/fatherhood (Cruz Pérez 2014) essentially because the first concepts are linked to the idea of the possible in the dynamics of being a father or mother, requiring no blood connection to

happen. That is, adoption appears in people's lives as a real and authentic possibility of parenting and filiation to be considered beyond pregnancy. Motherhood/fatherhood is a biological, physical process, based on blood ties, which unites parents and children, genetically. Some people are still unable to signify the possibility of becoming parents without blood ties. However, and due to the visibility that adoption has gained more and more all over the world (Riley and Van Vleet 2012), people have built new meanings in the face of the impossibility of generating their children biologically, ranging from different conceptual methods to adoption.

The idea of the possible (see section "The Possible in Psychology"), in a sociocultural and developmental approach, suggests that we are in worlds "infused by a sense of possibility, worlds that are open to alternatives and largely indeterminate futures" (Glăveanu 2021, p. 2). In adoption context, these different alternatives must be understood from different perspectives (see section ► "Perspective"), not only in the perspective of the social position of future adoptive father/mother, but also in the children and adolescents' perspective who wait in foster care institutions for their future adoptive parents.

Brief Adoption Considerations

Adoption is a sociocultural phenomenon that has occurred in all societies for a long time. In its most remote origins, adoption or similar cultural practices had an eminently private character, with little or no state intervention. In these dynamics, the will of the parties involved (donors of the child, intermediaries, and adoptive parents) prevailed and "the interests of adults were predominant, enduring in such molds for centuries and centuries" (Figueirêdo 2009, p. 149).

The first regulation that has history is in the Code of Hammurabi, King of Babylon (1728–1728 BC). It also appears in the Hindu Laws of Manu, written about 200 BC. In Greek and Roman societies, adoption was linked to religious beliefs, and to the need to worship the ancestors, so that the family would not be

extinguished (Bandeira 2001). "Perhaps the earliest known adoption is mentioned in the Bible, which describes the adoption of Moses by the Pharaoh's daughter" (Adamec and Miller 2007, p. xxi).

It is from Christianity, with the promise of life and eternal abodes in heaven, the fear of those who had no descendants was eliminated, and this diminished the practice of adoption at the time. In the Middle Ages, the Catholic Church created the Baby Hatch to welcome abandoned babies and guarantee the anonymity of the parents, in an attempt to reduce infanticides of the time. Adoptions remained low (Weber 2003). In the Modern Age, adoption was again accepted and, slowly, it started to be legislated through some norms – the codes promulgated by Cristiano V, in Denmark, in 1683; the Prussian, in Germany, in 1751; and the Codex Maximilianus, in Bavaria, in 1756. Adoption was only in fact again in the limelight after the French Revolution (1789), a movement strongly influenced by the Enlightenment principles of freedom, equality, and fraternity.

We find adoption also present in mythology (Oedipus, Hercules, Romulus, and Remus), in fiction (Oliver Twist, Superman, Spiderman, Harry Potter, Despicable Me, Kung Fu Panda, etc.), and even in books considered sacred (Bible: the adoption of Jesus Christ and Moses). This scope of adoption "is testimony to its existence in all places and times and to its ability to excite the imagination" (Novy 2004 in Palacios & Brodzinsky, 2010, p. 270).

Adoption as a cultural system, in the light of anthropology and sociology, when investigated in various societies, reflects the social structures, the process of organization of societies and the global processes that involve changes in family norms and in the construction of families. Adoption has been practiced and legislated in different ways over time, always mediated and regulated by cultural, social, political, economic, legal, and psychological aspects (Valério 2013). New demands for the adoption institute continue to emerge, such as, for example, homosexual couples who wish to adopt or the fight in defense of the rights of children and adolescents, who have become the focus of adoptions, inverting the secular logic that

adoption was, first of all, to meet the needs of unhappy people who could not have children.

The success of adoptions requires adequate preparation for both future parents, as well as the children and adolescents available for adoption, and post-adoption follow-up and support. Brazil has a successful experience regarding the preparation of applicants and post-adoption support for adoptive families: The almost 200 Adoption Support Groups (*GAAs*), formed essentially by adoptive families, applicants for adoption, and professionals in the areas of law, social work, psychology, and pedagogy, offer voluntary monthly meetings of psychological and socio-legal preparation, events, as well as face-to-face and virtual assistance and have helped countless families recently graduated from adoption. Also, it works to raise awareness in society on the issue of adoption, promoting the reframing of myths and beliefs (To learn more: www.angaad.org.br). This type of adoption-oriented service represents a space for reflection, in which prospective parents can consider multiple possibilities and challenges of adoption. In other words, this Brazilian initiative promotes the necessary conditions for society, especially future parents, to consider adoption with its specificities, as an authentic and legitimate form of parenting (Valério 2013; Valério and Lyra 2016).

Faced with the coexistence of contradictory messages, for and against adoption, circulating in the collective culture, those who decide to adopt face a feeling of ambivalence, as these messages, according to Valério and Lyra (2016), can play a central role in the construction of meanings on adoption, by claimants. In this process, people need to reflect on the different perspectives that are posed from different social positions.

Adoption and Its Relations with the Possible

When we talk about adoption, we cannot reduce this phenomenon to a single legal act of transferring family power to new parents. We are talking about experienced mourning, both by people who wish to adopt (mourning of not generated

children) and by children and adolescents who have lost or never had the protection of their parents. We also talk about future wishes and plans. Some applicants believe they can only adopt a newborn, girl, White, and healthy child. Andrei (2001) calls it “child of the fairies” (this idea is closely linked to the bad blood myth. The parents wish to adopt a pure child). This belief means prejudice against older, Black, not healthy children, and adolescents who are available to adoption but are doomed to stay in shelters by the adoption-dominant perspective.

Establishing theoretical relationships between the adoption institute and studies of the possible is to reflect on how to break with the dominant cultural form (becoming pregnant) of becoming a father and mother. Based on the theory of the possible, proposed by Vlad Glăveanu (2018a, 2018b, 2021), we started to broaden our understanding of the sociocultural dynamics of adoption. According to this same author (2021), when we relate to the world, in most cases, we act from culturally consolidated forms, we play the roles legitimized by society, and “we reinforce the sameness” (p. 2). Then, Glăveanu proposes that we adopt:

a different perspective from the one we (usually) hold. Exploring the “gap” between two (or more) perspectives on the same object or situation holds tremendous transformative and developmental potential. Most of all, it transforms the singularity of relating to the world, thinking and acting in a certain manner, into multiplicity. Becoming aware of the space created between two or more perspectives is a precondition for engaging with the possible. (p. 3)

Glăveanu (2021) advocates that imagining possible futures such as becoming parents requires a dialogical relationship between the self and others. From this dialogue between the position of future parents and the world (others), the person can access a world of alternatives, through imagination (see section ► “[Imagination](#)”), expanding possible futures, and not just being dominated by a perspective from a socially dominant position – in this case, to be a parent, the mother must become pregnant. Therefore, in this dynamic, people must be able to perceive different perspectives and start to consider them together,

making them dialogue with each other. One possible way to start considering adoption – non-blood ties perspective – is through participation in adoption support groups (*GAAs*), and meeting adoptive families and even studying the topic. In this way, adoption will become a possible alternative, just as the blood ties perspective.

This evokes an ethical dimension of what is possible for adoption, that is, the possibilities of becoming a father/mother by biological means (becoming pregnant, drug treatments, surrogacy, artificial insemination, in vitro reproduction, etc.) are no longer in a power relationship, where they are validated as authentic and superior, and adoption – characterized as a form of affiliation based on affection and unrelated to biological ties – starts to be among the possible forms of becoming a parent, not being considered of less value and shrouded in myths and prejudices.

Finally, we highlight that the emergence of the possibility arises from the gap between different positions and perspectives that are placed in the collective culture in a given time-space. For example, the act of stealing a child to adopt is not considered a possibility. Thus, examining the possibilities mentioned above – the biological pathway and the path of adoption – we can see that the choice made by people is dynamically related to the perspectives of the meaning that this adoption plays for each one. We call these possible paths that exist in society as avenues of directive meaning – ADM (Lyra et al. 2018) – that expand or limit the diversity of perspectives built by each person in the face of adoption. This aspect related to the different perspectives of the possible highlights the relationship between the person (the adopter) and the meanings that hover in society.

From the Dominant to the Nondominant Perspective in the Sociocultural Construction of Parenting

In a survey carried out by Valério (2013) on the decision to adopt legally, heterosexual couples pointed to pregnancy as the first perspective

considered when they wished to have children. This finding corroborates studies in the area that point to the impossibility of giving birth to a child, as the main motivation for adoption. We need to highlight in these studies that adoption, for those who cannot get pregnant, is the last option considered, most of the time. People desperately fixate on blood ties perspectives, and that has a *raison d'être*. Blood ties were and are extolled in different cultures, legitimizing the hegemonic blood tie perspective. To illustrate the repercussions of this thought, we see the quote from a person who was unable to conceive, with failed attempts at artificial insemination and who did not yet consider adoption:

Sarah: There are also people who advise us to adopt as if adoption were, you know, a consolation prize. And it is not just from this angle that we would like to adopt. 'Ah, you can't get pregnant, so ... adopt.' [...] I understand their point of view, since they see our desire, and they want us to be happy, so they try and find a solution right away. (Valério and Ferreira-Novaes 2018)

The above quote, present in the study by Valério and Ferreira-Novaes (2018) on the construction-destruction semiosis of hierarchical systems, emphasizing preserved traces of destroyed signs (valuation of genetic affiliation) in the emergence of the transition toward the decision to adopt and the creation of a new sign (adoptive filiation being feasible), reveals how the process of deciding to adopt is enveloped by signs present in the collective culture that regulate this dynamic in the construction of parenting. Sarah's position reinforces the blood ties perspective by constructing her meaning about adoption.

The Relational Dynamics Between Perspectives

When deciding to have children, as already discussed above, the first idea that comes to mind, mostly, is to get pregnant, is to follow the social script, what is expected and culturally agreed. For adoption to enter the scene, it is necessary that another perspective, in addition to the blood ties, starts to figure in the possibilities of

Adoption,**Fig. 1** Perspective for parentality construction: blood ties X non-blood ties

building parenting, so that it is not understood by future parents, as the last option. It is necessary to understand the transformative importance that the studies of the possible bring to the social reality not only of future parents but, mainly, of institutionalized children and adolescents.

Sávio Bittencourt (2010), then a public prosecutor in Rio de Janeiro, Brazil, stated that biology justifies inertia and kills childhoods. This strong position of the prosecutor and father by adoption, alerted to the defense of the dominant perspective by social actors of the Brazilian reception system, also highlighted the role of childhood judges. For him, insisting several times on the child's return to his biological family, because children should remain with their blood families, results in long periods of stay in welcoming institutions, depriving them of the affection and security of a family, for example. Several Brazilian judges and legislators, awakened to this problem, have recently limited the time given to the child protection network to carry out various actions, for example, the removal of family power – an action that precedes

the insertion of children and adolescents in the that country's national adoption system.

The emergence of a new perspective is quite complex, mainly because it normally comes from a space of resistance (Glăveanu 2018b). It is not our intention to discuss this phenomenon here but to highlight the developmental dynamics involved in the sociocultural theory of the possible. See Fig. 1, below:

Describing Fig. 1, we start with the proposal of two divergent perspectives in the dynamics of the construction of parenting. The dominant perspective, we call blood ties, encapsulates all forms of parenting and affiliation that maintain blood ties in family tradition. In opposition to biologism, we propose the non-blood ties perspective that is nondominant in the context presented. These different possibilities coexist in the construction of imagined parenting, that is, in the construction of a possible future. By dialogically exploring the space between these different perspectives, we explore the reality on a given theme (for example, becoming a father/mother),

adapting us to the physical world in which we live, and, at the same time, allow us to think and act within it based on a perception of not only how things are but how they could be, will be, and could never be. (Glăveanu 2021, p. 56)

We observe that adoption emerges as an alternative resulting from the dialogue established between the dominant and nondominant perspectives, in the context of building parenting. Illustrating this dynamic, consider that someone who wants to be a mother or father has not even considered any possibility other than pregnancy. But that person cannot get pregnant, so he faces a dilemma. What to do? The possibilities by the collective culture range from drug treatments, assisted reproduction, and adoption, but the last one figures, mostly, as the last possibility or as a nonpossibility of choice. There must be at least two different perspectives for the person to reflect on other possibilities for the future and, subsequently, to choose what to do. This dynamic characterizes the agency (Glăveanu 2021) highlighted by the theory of the possible. Through the imaginative process, the person expands his experience (Zittoun and Cerchia 2013) of the here and now, starts to share other realities by accessing past experiences (lived by him or others), and also imagining possible futures (Zittoun and Gillespie 2016).

Returning to Sarah, after recognizing their infertility and inability to conceive, she and her husband expand their experience, moving away from the here and now and starting to consider new possibilities and begin a process of choosing for adoption:

Sarah: I think, of the two of us, I resisted a lot more, because of ... fulfillment, for being a woman, and everything else ... But from the moment I realized that he was open to adoption, I started opening up too. And my previous way of thinking: "I'm not adopting right now, I'm not going to think about adoption" because people would think: "Oh, she couldn't get pregnant, so she adopted" to ... 'make up for it' ... No, I changed my mind ... I don't even want to know what people are or aren't thinking! [laughs] Let them think what they want I ... What I want today is ... to find, embrace a child whom I will love with all my heart ... [both get emotional]. (Valério and Ferreira-Novaes 2018, p. 92)

In this dynamic, as shown in Fig. 1, the choice made – adoption – also presents different

perspectives. The first perspective presents what is still dominant, about the profiles that Brazilian applicants for adoption want: newborns, White children, girls, and healthy (child of the fairies). Nondominant perspectives – gathered here in Fig. 1, in the non-blood ties perspective – collaborate so that the person can engage in a perspective-making process, that is, to consider different possibilities. This psychological and cultural process occurs from the initiative of putting in the position of the other – in this specific case, it can be both people who have already adopted this dominant view, adopting groups of siblings, older children, teenagers, and unhealthy children, for example, but also from the position of children and adolescents waiting to be adopted. Here are the developmental dynamics in the process shown in Fig. 1. With each choice, or perspective taken, made (adoption) after the dialogue established between different perspectives (blood ties, non-blood ties). According to Glăveanu (2021), a new space of possibility is formed (adoption: dominant, non-dominant) and, therefore, the same sociocultural and semiotic process will occur.

Conclusion

In the relationship between the studies of the possible and the adoption, we observed that the diversity of perspectives, in the first place, contributes to reflection and practical solutions concerning the needs of children and adolescents available for adoption. Adoption, when it takes into account the position of the other, requires that we consider not only the wish of the suitors (they usually imagine a way of replicating what biology has denied them and wish to adopt a newborn), but that possibilities pass appear together, with nondominant perspectives also considered. The others, that is, children and adolescents to be adopted, are now seen and considered in this dynamics. Always making it possible to open up to different perspectives allows the emergence of new unimagined possibilities. Cultivating spaces between different perspectives on adoption opens up just the possibility in which the new can emerge.

Keywords

Adversity · Suffering · Artistic creativity ·
Posttraumatic growth · Possibility

Definition

Throughout time, experiences of adversity and suffering have been associated with creativity, particularly that of an artistic nature. This dynamic has also been the subject of considerable scientific inquiry. The archetype of the “tortured artist” is ubiquitous as is the notion that great art is born out of adversity. There is evidence to suggest that creativity can arise following traumatic events and that experiences of adversity can inspire and provide source material for the creation of art. Additionally, experiences which challenge preconceptions can engender alterations at a neural level and bring new creative possibilities to fruition. The romanticization of suffering is however problematic, and it should not be suggested that physical and psychological distress are desirable prerequisites for creativity. Indeed, positive experiences can also be creatively transformative. Nevertheless, as suffering is a universal experience, it is important to better understand the

mechanisms and contributory factors which allow individuals not only to recover but grow creatively in the aftermath of painful and traumatic events. Cultivating such understandings may provide a sense of hope and comfort as well as enabling creative development and the expansion of human possibility following adversity.

Introduction

Associations between experiences of adversity and creativity have been prevalent throughout history and the subject of extensive scientific investigation. The notion that ascension can occur through suffering is metaphorically exemplified by the mythical phoenix rising from the ashes. Creativity may be defined as the generation of novel and useful ideas or products (Sternberg 2006). Many accounts of the challenges endured by creative individuals suggest that they can use challenging experiences as sources of inspiration and motivation for their work. The “art born of adversity” troupe is ubiquitous, and many plays, films, pieces of music, and works of visual art may be interpreted as attempts to find meaning in suffering (Sandholm-Bark 2020). Through creating art, human beings seek to make sense of incomprehensible tragedies, which are an inevitable part of life (Ghadirian 2009). The individual and collective quest to understand the darker aspects of existence can manifest in acts of creativity and give rise to previously unimagined possibilities.

This entry will explore the relationship between experiences of adversity and artistic creativity. It will discuss empirical evidence for this association and outline relevant theoretical frameworks. The detrimental effects of adversity on creativity will also be considered as will the notion that positive experiences may be transformative. Underlying mechanisms and determinants, including personal factors which may contribute to the phenomenon of adversity leading to creativity, will also be examined. Additionally, the interrelationship of creative engagement and personal development in the aftermath of trauma will be discussed.

Detrimental Effects of Adverse Experiences on Creativity

Adversity may present new opportunities for creative possibility, such experiences should not be romanticized. They can be painful, psychologically traumatic, and have detrimental long-term effects. For example, exposure to childhood adversity (e.g., abuse, neglect, etc.) has been associated with multiple medical and psychiatric problems (Felitti and Anda 2010; Herzog and Schmahl 2018) as well as increased morbidity and mortality (Merrick et al. 2019). Even resilient people who are exposed to trauma show heightened cardiovascular reactivity to trauma reminders (Tucker et al. 2007) and greater vulnerability to PTSD with subsequent trauma exposure (Bremner et al. 1993). They may also experience cognitive decline (Stein et al. 2002), altered catecholamine levels (Otte et al. 2005; Young and Breslau 2004), more chronic illness later in life, and decreased mean life expectancy (McFarlane 1997). In support of the long-term ill-effects of adversity, a meta-analysis of 161 studies of 81,866 refugees and other conflict-affected people (e.g., asylum seekers, veterans etc.) internationally found that the mean prevalence of PTSD was 30.6% (Steel et al. 2009). Rather than being ideal for the cultivation of creativity, such conditions can engender considerable disability and incapacitation.

The ubiquitous myth of the “tortured artist” implies that suffering (mental and/or physical) is a prerequisite for creativity; however, this premise is contentious in the literature and is best regarded with skepticism (Akiskal and Akiskal 2007). It aligns with the Nietzschean notion “That which does not kill us makes us stronger,” which has become deeply ingrained in the cultural imagination and entered common parlance. Such stereotypes are damaging as they negate the depth of suffering and distort the reality of lived experiences (Silvia and Kaufman 2010; Weston and Imas 2018). Moreover, the notion that hardship is “character-building” may simply be attributable to the human need to ease suffering by rationalizing it and cultivating positive illusions (McFarland and Alvaro 2000). The objective of

this chapter is not to ennoble suffering or present it as a desirable precondition for creativity, but to impart that adversity is not necessarily hopeless and can present unexpected creative possibilities (Eggerman and Panter-Brick 2010; Kleist and Jansen 2016).

Evidence of a Relationship Between Experiences of Adversity and Creativity Possibility

While experiences of trauma and adversity may not be desirable, many people show remarkable resilience and can even thrive in the aftermath of traumatic events; indeed, most trauma survivors do not develop PTSD, and up to 70% report positive psychological growth (Linley and Joseph 2004). The term “posttraumatic growth” (PTG), defined as the positive psychological change that is experienced due to the struggle with highly challenging life circumstances, is now widely used to describe this phenomenon (Henson et al. 2021). Five domains of growth have been described, namely: appreciation of life; relating to others; personal strength; new possibilities; and spiritual growth (Taku et al. 2008). Importantly, heightened creativity is one possible impact of growth in these domains.

Biographic and historiometric literature also indicates a relationship between adversity and enhanced creativity. Adverse experiences are a recurrent theme in biographies of eminent creative individuals. For example, many artists with mental illness have had emotionally tumultuous childhoods which are explored in their artistic works (Ludwig 1992). A further ubiquitously referenced example is the work of artist Frida Kahlo which reflects her lived experiences of chronic pain, loss, and disability throughout her life (Conaty 2015). People pursuing creative work (especially in artistic fields) tend to report higher than average incidence of challenging life circumstances, including adverse life events (Simonton 2014) and psychological disorders (Andreasen 2008; Jamison 1993; Johnson et al. 2012; Ludwig 1992). Such findings parallel those of Zausner (1998) who conducted a qualitative analysis of biographies of eminent

artists suffering physical illness. Findings were that experiences of adversity provoked disequilibrium and necessitated alternative means be found to fulfill creative ambitions. This conceptualization also aligns with the ancient association between creativity and physical stress which has been termed “creative illness” (Ellenberger 1970). For example, the stress of a cultural initiation is thought to engender profound psychological changes and ascension to a higher level of functioning (Zausner 1998).

The relationship between adversity and creativity is not limited to eminent individuals, as demonstrated by Forgeard (2013) who examined the impact of adverse life experiences (e.g., disaster, illness, accidents, and assault) in the general population in the United States ($n = 373$). Findings indicated the number of adverse life events predicted self-perceived creative growth as well as breadth of creativity. These findings are aligned with those from an exploratory pilot study focused on a Rwandan sample ($N = 100$) of genocide survivors (Blackie et al. 2015). People seeking mental health services were asked to indicate the extent to which they perceived that their creativity had increased since the genocide. Moderate increases were reported by 25% of participants. Notably, about half referenced music or singing, with the remaining references including creative writing, poetry, dancing, crafts, artisan skills, and increased ability to generate new ideas or projects.

The concept of “adversity capital” offers a way to think about how individuals gain agency and sustain themselves despite ongoing hardship (Walsh 2016). Disadvantaged communities can be highly creative in surviving precarious conditions (e.g., entrepreneurial practices following the global financial crisis) (Garcia-Lorenzo et al. 2018). The poor and marginalized can use creative survival tactics to navigate challenging situations (e.g., poverty, war, climate change, etc.) to actualize opportunities and exploit resources (Jones et al. 2010; Vigh 2010). Equally, disenfranchised communities can subvert oppressive forces through practices of resistance, including the creation of art (Imas and Weston 2016). For some, artistic creativity can be a means of overcoming

marginalization and communicating the pain associated with it (Csikszentmihalyi et al. 2018).

The historical archive also provides evidence for the notion that creative possibilities arise from adversity. Difficult periods including wars, political protests, and global pandemics have led to cultural turning points where artists have been at the forefront of change. Following times of upheaval, the arts have not only survived, but flourished. The Renaissance is a powerful example of this. During the fourteenth century, the bubonic plague swept across Europe, killing at least one third of the population (Ziegler 2013). This human tragedy also engendered socio-economic, cultural, political, scientific, technological, and religious changes and contributed to one of the greatest epochs for art, architecture, and literature in human history (Burckhardt and Middlemore 2019). Confrontation with mortality engendered an appreciation of the finitude of existence and a desire to enjoy life's pleasures. Many people sought solace in art and literature and members of the elite became patrons of the arts. The rediscovery of classicism and the increased secularization of society during this time were also reflected in conceptual and aesthetic shifts in artworks that were created (Paoletti and Radke 2005). This is exemplified by masterpieces such as Botticelli's *Primavera* (c.1470-1480) and *The Birth of Venus* (c. 1484-1486) and Da Vinci's *Mona Lisa* (c. 1503-1506). Thus, after the initial horrors of the plague, Italian society became richer than before.

A certain amount of stress can be beneficial to creative productivity at a more mundane level. Those in many creative professions continuously face constraints, and some even argue their creativity manifests in coping with external pressures (Glück et al. 2002). For example, the pressure of having to meet an exhibition deadline may motivate an artist to finish a particular body of work. The imposition of external constraints may elicit an optimal level of physiological arousal and in so doing enhance creative performance. Support for this idea comes from organizational psychology research suggesting an inverted U-shaped relationship between time constraints and creativity (Baer and Oldham 2006).

Evidence presented in this section collectively suggests an intimate connection between experiences of adversity and creativity on personal and collective levels. It indicates that negative experiences can be channeled into creative survival strategies as well as artistic expression. For both individuals and societies, creativity can become an act of turning challenge into opportunity.

Theories and Mechanisms

Theoretical models have been developed to explain how creative possibility can arise in the aftermath of adversity. Four relevant and comprehensive models will be discussed. Two of these models raise questions as to whether the relationship between creativity and adversity is genuine or illusory. First, Cognitive Adaptation Theory proposes that individuals faced with threatening events cope by developing and maintaining self-enhancing illusions or narratives of personal growth that do not, in fact, relate to verifiable positive changes (Taylor 1983). Second, and conversely, Organismic Valuing Theory proposes that human beings have an innate tendency to integrate adverse experiences into a unified sense of self, and through this process, genuine growth occurs (Joseph and Linley 2005).

Assumptive World Theory also proposes that adverse experiences can shatter individuals' beliefs about the benevolence and controllable nature of the world (Tedeschi and Calhoun 2004). Additionally, they instigate the reexamination of core beliefs, hopes, and aspirations and can be conceptualized as metaphorical earthquakes (Cann et al. 2010; Janoff-Bulman and McPherson Frantz 1997). According to Assumptive World Theory, adversity instigates "psychologically seismic" restructuring that is necessary for growth (Tedeschi and Calhoun 2004). People make sense of their experiences through the cognitive integration of new information which allows the modification of preconceptions. Recovery therefore does not equate to returning to an earlier way of being but rather establishing a new assumptive world that incorporates the traumatic experience.

Zoellner and Maercker (2006) have advocated a two-component model which accounts for discrepancies between the actual and illusory models of growth in the aftermath of adversity. According to this model, PTG has both constructive and illusory aspects. It posits that a transiently distorted perception of growth initially buffers the effects of a stressful event soon after it occurs. Illusory growth is thought to decrease with time if actual PTG is not experienced, whereas actual PTG increases or remains consistently high with time. Thus, both actual and illusory models contribute to understandings of how the phenomenon of creative growth in the aftermath of adversity may occur.

A possible mechanism underlying the relationship between adversity and creativity as manifestation of PTG is that of neuroplasticity (Ord et al. 2020). Neuroplasticity is understood as experience-driven, time sensitive, and influenced by environment and internal states, such as motivation and attention (Ruge et al. 2012). Neuroplasticity is thought to be responsible for the functional and structural changes in the brain accompanying PTG. For example, neuroimaging has identified positive associations between PTG and increased gray matter volume in the right prefrontal cortex (rPFC) and higher resting activity in the central executive network (CEN) (Fujisawa et al. 2015; Nakagawa et al. 2016).

Alterations in neural connectivity may allow new ideas and associations to be formed which may in turn inform artistic creativity. Imaging studies indicate potential overlap between brain regions associated with PTG and those involved with creative cognition and behavior. For example, the CEN is thought to play an important role in artistic creativity (Beatty et al. 2015). Moreover, studies on artistic creativity support the role of the rPFC and parietal cortical regions in visuospatial perception and processing (Bhattacharya and Petsche 2002; Ng et al. 2001).

Creative engagement may also support PTG and constitute a form of “neuroenhancement” in the aftermath of trauma (Garrett 2020). The brain has the potential to change in a positive way through exposure to creative activities. Lusebrink

(2010) found that the arts play an integral role in activating specific neural structures such as the occipital lobe and basal ganglia, along the limbic regions and sensory areas of the cerebral cortex. The capacity of artmaking to foster neuroplasticity may be partially attributable to the wide range of novelty exposure available. Lusebrink stated, “An expression through art media can also originate from complex cognitive activity involving decisions and internal imagery, thus activating the sensory channels and motor activity” (Lusebrink 2004, p. 192). For example, with painting alone there are endless possibilities in relation to how media can be used to facilitate different forms of expression, which result in the activation of “sensory channels” and innovative ways of thinking (Lusebrink 2004). Thus, creativity and cognitive adaptability cultivated through artistic engagement may enable experiences of adversity to be coped with in a more adaptive manner.

Contributory Personal Factors

Questions remain about how, and for whom, adversity can lead to the augmentation of creative possibility. Factors including personality may play a role in determining whether an individual might grow and/or deteriorate following adversity. Indeed, the trait of openness to experience, which is a predictor of creative thinking and achievement (Kaufman 2013; Silvia et al. 2009), also predicts the identification of new possibilities for one’s life, and perceptions of increased personal strength (Christensen 2020; Tominaga et al. 2020). Increased openness to experience may therefore allow trauma survivors to think more creatively about future opportunities for growth. In addition, an increased sense of personal strength may promote feelings of initiative that is beneficial to creativity, or, alternatively, creative engagement may enable mastery, thereby increasing self-efficacy and self-esteem (Zausner 1998).

Personal characteristics, such as sensitivity, may predispose individuals to experiencing

creative growth in the aftermath of adversity. For example, those with sensory processing sensitivity (SPS; Aron and Aron 1997), a biological predisposition involving deep processing of stimuli, which leads to overarousal, intense emotions, and heightened physical sensitivities, has been found to be more susceptible to experiencing post-traumatic stress (Booth et al. 2015; Grinapol et al. 2022). They may also, however, be more inclined to experience PTG (Gilbert 2021).

Cognitive processing and the capacity for exploring thoughts and feelings surrounding an event are also key factors which allow adversity to be turned into advantage (Caspari et al. 2017). Negative psychological coping strategies (e.g., regret, upward comparison to others, etc.) have been positively correlated with posttraumatic stress severity, while positive strategies (e.g., acceptance and resolution) have been negatively related to posttraumatic stress severity, but positively to PTG (Ogińska-Bulik and Michalska 2021).

Having time to reflect on and process stressful or painful experiences may also impact creative growth (Cox and McAdams 2014). Though psychological and physical suffering can be creatively detrimental when experienced, perceptual shifts and creative development can occur when conditions can be managed or overcome, and retrospective reflection can occur (Forgeard 2013). For example, those who achieve creative eminence in their fields do not operate optimally when experiencing severe mental illness (Andreasen 2008; Rothenberg 2006). Periods of creative productivity tend to arise when individuals are either transitioning out of or between depressive episodes as opposed to during acute psychological distress (Andreasen 2008; Jamison 1989). Such findings highlight the importance of having distance from experiences of adversity, for creativity to flourish as a manifestation of PTG.

The type of rumination engaged in following a traumatic experience also appears influential. According to Assumptive World Theory (Tedeschi and Calhoun 2004), individuals engage in two forms of rumination following experiences of adversity. *Intrusive rumination* refers to the

occurrence of unwanted thoughts related to the event, whereas *deliberate rumination* refers to purposeful thinking about the implications of the event. Intrusive rumination predicts higher levels of distress (Taku et al. 2008) whereas deliberate rumination predicts growth (Calhoun et al. 2010; Cann et al. 2010). Intrusive rumination has also been associated with a decline in all five domains of growth (appreciation of life; relating to others; personal strength; new possibilities; and spiritual growth) while deliberate rumination has been found to lead to an increase in all five domains (Forgeard 2013). Long-term growth may therefore follow or coincide with distressing experiences and be facilitated by activities which minimize intrusive rumination – such as creative engagement which can focus attention away from personal suffering.

Adverse experiences may also provide source material, ideas, and inspiration for the realization of creative projects. For example, many artists use their work to express their emotions (Blok 2017). Some have even used their own bodies and physiological experience as source material for creative projects (e.g., *Heart* (2014) by Lisa Roet which uses echocardiogram and MRI footage of the artist's own heart). The creation of art can enable traumatic experiences to be contemplated, processed, and expressed. By engaging in creative work, people can heal and grow from the challenges that have befallen them. Such creative callings motivated by past adverse experiences may therefore constitute a form of “survivor mission” (Eskreis-Winkler et al. 2014). Experiences of adversity can also expand the scope of possibility for artistic creativity indirectly. Even if such experiences are not directly represented, they can engender the cultivation of empathy, emotional depth, and perspicacity which can in turn lead to more sophisticated works of art.

The evidence presented in this section highlights individual differences in the extent to which trauma leads to creativity. An important future line of research is to understand more comprehensively the breadth of environmental and personal factors that determine which individuals turn adversity into creativity, and how this occurs.

Facilitating Possibility Through Creativity in the Aftermath of Adversity

Nurturing creativity can help people understand, overcome, and grow from adversity (Kaufman and Gregoire 2015). Creative engagement confers benefits for physical and psychological well-being (McFadden and Basting 2010; Stuckey and Nobel 2010). It can increase flow, catharsis, distraction, positive emotions, and meaning making. Creative immersion, and the attainment of a flow state, can be emancipatory, providing a refuge and means to overcome physical and psychological pain (Csikszentmihalyi et al. 2018).

Imaginative aspects of artistic practice can augment coping strategies that promote adaptive resilience and enhance psychological wellbeing (Thomson and Jaque 2019). Expressive art therapy practices use the creation of visual art to facilitate cognitive processing of traumatic events and alleviate distress (Chiang et al. 2019). Engagement with literary, visual, and the performing arts can be reparative in the face of traumatic exposure, and provide opportunities to find meaning, bring order into emotional chaos, and regain a sense of control (Forgeard 2013; Richman 2014).

Given that creativity in the wake of adversity has been associated with introspective reflection and deliberate rumination, it may also be beneficial to support these processes using psychotherapeutic approaches. For example, Metzl and Morrell (2008) position creative thinking as a characteristic that can be taught and developed to enhance resilience following adversity to increase life satisfaction and reduce clinical distress. Similarly, Hunter (2001) suggests that it may be helpful to view adversity as a challenge that can be overcome through being creatively courageous. Thus, collectively, the existing literature suggests creativity may constitute both a manifestation of and means to attain PTG.

Positive Experiences and Creative Possibility

This chapter has highlighted that adversity can engender creative growth, and the PTG model

focuses on the potential positive changes following highly stressful experiences. However, research indicating that creativity can also be fostered through positive emotional experiences should be acknowledged. The idea that positive emotions are possible catalysts for growth has been explored by different theoretical frameworks in recent years, including the broaden-and-build theory (Fredrickson 2001) and the “inspire-and-rewire” hypothesis (Keltner and Haidt 2003). Fredrickson’s (2004) “broaden-and-build” theory contends that positive emotions broaden awareness, enhance neural connectivity, and encourage original thoughts and actions. The complex emotion of awe, for example, has been associated with moments of personal change (Schneider 2009; Chirico 2020). It is proposed that being confronted with extraordinary vastness challenges and expands individuals’ mental frames (Chirico et al. 2018; Silvia et al. 2015) and in so doing helps them find new connections among objects and ideas. Experiences of awe may therefore be related to creative thinking and behavior (Chirico et al. 2018).

A parallel concept to PTG is the postecstatic growth model which explores the positive psychological changes after emotional peak experiences such as love, joy, and awe (Roepke 2013). Postecstatic growth is thought to occur in specific areas, namely spirituality, meaning, social relationships, and self-esteem. Considering the overlap between these perceived benefits and the positive psychological effects that can follow highly stressful events, PTG and postecstatic growth may be similar processes (Mangelsdorf and Eid 2015). Therefore, those who are more likely to experience PTG may also be more likely to experience postecstatic growth and vice versa. Meta-analytic findings from 122 longitudinal studies (Mangelsdorf et al. 2019) showed increases in self-esteem, positive relationships, and mastery after both positive and negative events. Furthermore, there was no evidence that negative life events have stronger effects than positive ones, indicating that people tend to experience psychological gains in the aftermath of impactful experiences irrespective of their emotional

valence. Similarly, Forgeard (2013) found that both decreases and increases in interpersonal relationships can lead to heightened self-perceptions of creativity. Taken together, these findings demonstrate that both positive and negative interpersonal events can provide rich raw material for creative works, especially in artistic domains.

Hence, creativity may not only arise in the aftermath of adversity but also following positive transformative experiences which result in existing schemas being challenged. The key element influencing growth appears not to be the emotional valence of the experience but rather its intensity and capacity to shift preexisting perceptions and understandings of oneself and the world.

Conclusion

This chapter has explored the association between experiences of adversity and creative possibility with reference to extant literature, theoretical frameworks, and mechanisms which may underpin the relationship. It has also highlighted the influence of personal factors in determining whether adversity is transformed into creativity. Additionally, evidence has been presented to suggest that creativity can be both an outcome of and means to attain PTG. The findings of the existing research do not romanticize suffering as a desirable prerequisite for creativity. Indeed, it is important to acknowledge that diverse experiences can function as an impetus for creative inspiration and expression – including those associated with emotions such as love, joy, and awe.

The findings presented in this chapter have broad implications, given that most people will experience adversity at some point in their lives. Understanding that suffering and trauma can be catalysts for healing, growth, and creative flourishing may provide a sense of comfort and allow the future to be approached with optimism. In the wake of trying times, many people could learn to thrive, and possibly reach creative heights they never thought possible.

Aesthetics

Maddalena Mazzocut-Mis
Università degli Studi, Milan, Italy

Abstract

Aesthetics is a philosophical discipline whose modern roots can be traced back to the first half of the eighteenth century, when Alexander Gottlieb Baumgarten thus named the “science of sensible knowledge,” forming a noun out of the Greek adjective *aisthetike*. He focused on the problem of sensation, recognizing that Aesthetics much be considered as its own specific field of inquiry whose laws can be recognized and, indeed, described (Baumgarten, *Meditationes philosophicae de nonnullis ad poema pertinentibus*. Halae Magdeburgicae: Litteris Ioannis Henrici Grunerti, acad. Typogr, 1735; Baumgarten, *Aesthetica*. G. Olms, Hildesheim, 1750). Aesthetics is thus caught between philosophy, **poetics**, and **rhetoric**, which had to

work hard to find its own independent location. The discipline's relative youth does not mean, however, that one can ignore its basis in classical philosophy, with which it has always been in dialogue from the **eighteenth century** onward. The great issues of Aesthetics, especially its reflection on **theories of beauty**, are rooted in classical thought, finding a full conceptual formulation and vocabulary in the **Enlightenment**, while augmenting reflection on creative processes within the arts and processes of reception. Through categories such as **beauty**, **ugliness**, the **sublime**, and **kitsch**, Aesthetics must come face to face today with a form of **art** whose borders are increasingly blurry and accept the disciplinary challenges laid down by neuro-aesthetics and technological hyper-realism, which are reanimating classical problems and terminology. Without being absorbed into new disciplinary and cultural horizons, contemporary Aesthetics is producing its own original standpoint, using its own conceptual tools to shed light on the new challenges that **art**, its **creation**, and **enjoyment** force us to confront.

Keywords

Aesthetics · Enjoyment · Taste · Creation · Genius · Aesthetic categories

History

If the meaning of the term “**art**” has changed over the course of history, Aesthetics does not attempt to establish what **art** may or may not be in terms of any rules or dogma. Instead, it takes account of the historical variation in that which people have considered to be **art** in any particular historical period, questioning those processes of understanding and interpretation connected to sensation, feeling, **emotion**, and the imagination, all of which play a role in reception/viewing and in the attribution of value to a **work of art**. The focus of Aesthetics is thus the entire field of experiences, actions, and processes that surround the production of a **work of art**, defining its identity,

symbolic meaning, and value: a field that concerns as much the **processes of creation** and production of **art** (including technical production) as it does the mechanisms for enjoying and evaluating art works.

The radical transformations to which the **concept of art** has been subjected by contemporary and twentieth-century artistic practices, its progressive expansion in which “**art**” is no longer necessarily an artistic production but instead the creative gesture as such (a gesture whose creativity also depends on the increasingly pervasive role of new technologies) have not freed Aesthetics from its task nor rendered obsolete its “historical” issues. Rather, **contemporary art** is posing new questions for Aesthetics, pushing the discipline to reflect in a critical and **consciously** theoretical manner on the changing relations between artistic activity and **reality**, values and creativity, as well as with the **art market**.

To return to the question of its origins, modern Aesthetics arose from the overcoming of the “classic” **idea of beauty** that was still dominant in seventeenth-century European culture. The intimate link between **taste** and pleasure that runs through the **eighteenth century** pushed many writers to reflect on the particular kind of pleasure that human nature can find in the contemplation of natural and artistic representations of the excessive, the deformed, the horrifying, shadowy and ugly, all of which are expressive and interesting for the receiver but cannot be traced back to the “classic” **idea of beauty** as order, the proportion of parts, and uniformity in variation. This is truer still in terms of the contemporary **experience of art**, which – along with historic avant-gardes – has definitively broken apart the constitutive relation between **art** and **beauty**, calling for new adequate **aesthetic categories** and parameters of judgment and evaluation.

There are, however, some overarching issues in Aesthetics that underscore its main principles and history, and from which it is hard to escape if one wants to provide an outline of the discipline: **creation** and **enjoyment** – or, put in another way, that which one makes or “invents” within the horizon of the possible, and that which one feels or senses.

One could claim that Aesthetics is the ability to have a particular awareness of things in such a way as to understand them through what strikes us or makes us feel **emotions**, qualities, similarities and differences: this becomes the initial moment of a game – a very serious game – which is more than mere hermeneutics. Here expression, **enjoyment** and **creation** appear on the one hand as a gift and on the other an obtainment from the standpoint of a subject who has applied all of their abilities and drawn on them through combining sensitivity, **taste** and judgment along the horizon of subjective choices. This has been the story of Aesthetics in modernity, a philosophical discipline able to provide expressive meaning to things and indeed that has been able to discover meaning inasmuch as it is the work of art itself that fills the subject's acts of perception with meaning, if (and only if) the receiver is ready to enter into a game of representation and expression. The rules of this game are never written, as Montesquieu (1757) and, after him, Kant (1790) demonstrated. It is from here that the flexible and alternating meanings, **emotions** and feelings derive. And yet, these uncertainties signal a precise journey, defined historically by a discipline that has made use of descriptive and interpretative categories, whose subjective horizon can often both be communicated and, indeed, shared.

Categorical System

An **Aesthetic category** – such as **beauty**, **ugliness**, **sublime**, **kitsch**, etc. – can be understood as a guide that assists the receiver/viewer in understanding the artistic universe. The attempt to categorize art does not, however, reduce its complexity to rigid schema but rather opens up onto a relational universe. If the authentic understanding of a **work of art** is not centered on a single moment but involved a heterogeneous quantity of motivations, categorization itself does functions as a means to not lose sight of the object and its justification, of the receiver and their feelings, despite the plurality of approaches.

Without any particular taxonomic expectations, the categorical system emerged when the

old system and hierarchy of the fine arts came to a close; in the **eighteenth century**, an important question was whether poetry or painting, sculpture of music was the more refined form (Batteux 1747; Diderot 1751; Du Bos 1719). The recognition of a plurality of values (intimately connected to the **crisis of beauty** and of the hierarchy of the arts) and the development of a reflection around particular aesthetic **categories** able to better interpret new artistic propositions, opened up perspectives that required redefining the **aesthetic object** as well as the **reception** and evaluation of a work.

We will examine three emblematic cases: the ugly, the **sublime** and the **kitsch**.

Ugliness can mean that which has not achieved its aim (which implies a value judgment), the unfinished (a technical judgment), that which is disappointing (a subjective judgment), that which is morally repulsive but technically perfect (a moral and technical judgment), the technical imperfect yet touching (a technical and subjective judgment), etc. (Rosenkranz 1853). There is a form of **ugliness** that we might call “pre-artistic” and an **ugliness** that is more specifically “artistic.” There is an **ugliness** of the thing itself and an **ugliness** of its rendering in art – and it goes without saying that the two things can also coincide, though not necessarily so. That which is usually ugly in nature can acquire a high level of **beauty** in art, as has been noted from Aristotle's *Poetics* onward. There is a functional **ugliness** and an anti-functional one, an **ugliness** through excess and another by defect and another still of waste. One might separate, in art, the **ugliness** of a work in its objectivity from the relative **ugliness** of the effects that this work solicits in the receiver, in their impressions and feelings.

In the theories of the eighteenth century, the **sublime** is very different from the highest form of **beauty**; instead it is the opposite of the idea of regularity proportion, harmony, form and balance. The **sublime** can even be defined as simultaneously pleasure and displeasure, a mixed feeling that is solicited in the subject by representations connected with the pain of others (Burke 1757). Still more than this, in a specifically Kantian language the basis of **sublime** is constituted by the idea of the “super-sensible”, an object

simultaneously of reason and feeling. Thus, there is a mathematical **sublime** (that which is large beyond all comparison) and a dynamic **sublime** (by which one measures oneself against the spectacle of nature as a power threatening fragile human existence). The **sublime** thus does not lie within any part of Nature but only within our soul, inasmuch as we can recognize ourselves as superior to Nature (Kant 1790).

Definitions of the **sublime**, however, do not stop with the eighteenth century. If the nineteenth-century **sublime** found the world of symbols, the twentieth-century version often referred to the metaphors of Lucretius, for whom the receiver of the **sublime** can be compared to a spectator observing a shipwreck (Blumenberg 1979). Comforted by their own position of safety, the subject conserves a certain emotional distance from that which they observe, even if in horror, allowing themselves an exclusively **Aesthetic** form of contemplation.

Within the **sublime** there thus exists a paradox that we can summarize in the following manner: “1. People avoid things that provide painful experiences and only pursue things that provide pleasurable experiences. 2. People have painful experiences in response to putatively **painful art** (e.g., tragedies, melodramas, religious works, sad songs, and horror). 3. People pursue putatively **painful art**. The paradox boils down to a simple question: If people avoid pain then why do people want to experience art that is painful?” (Smuts 2009). In the history of Aesthetics there are at least two main ways to solve this paradox: the meta-response theory and the conversion theory. The first states that terror and fear are negative experiences which are effectively painful for the subject experiencing them, while pleasure is a meta-response to them. “[...] [T]he meta-response is a recognition of our capacity to feel emotions appropriately – to pity someone in a tragic situation”, stimulating our sense of humanity. This fact arouses a meta-reaction in us: the satisfaction in finding ourselves to be moral beings. According to conversion theory, however, emotional activity is pleasurable even if it is provoked by the sight of ugly or imperfect objects, simply because it makes us aware of a level of **reality** higher than ourselves (Brady 2013).

Through reflecting on the representation of **ugliness** and the **sublime**, Aesthetics responded to an important question: can pleasure be found in that which is unpleasant and, if so, how can one understand the connection of judgment therein?

Both the **sublime** and the ugly share a sense of painful tension; yet from a qualitative and quantitative point of view, the ugly is strikingly different due to its resigned outlook, the lack of heroic tendency and high-sounding ethical moments, for its contained development of any form of **empathy**. It is possible (indeed, this is the case for many artists) to see connections with the caricature and grotesque within the ugly, even connections with the disgusting due to the profane tension that animates it.

In our own period, “**ugliness**” is increasingly an indicator of a vast range of artistic effects whose features – even if they can be described – are becoming increasingly blurred and uncertain. Under the wide umbrella of the ugly we find a complex and contradictory amalgam. Ever since so-called beautiful art came to terms with the **art market**, **ugliness** has become characterized as the tawdry and vulgar, becoming increasingly similar to **kitsch**.

Kitsch is a container of imitations that has to serve the function of immediate pleasure. Prefabricated words, expressions, attitudes and situations used a 1000 times over: everything becomes a cliché within a world of consolidated conventions. **Kitsch** mimics. With an increasing Platonic distance from the truth, it copies the artifact and makes it available to everyone. For the receiver, **kitsch** is a pleasing image that protects and intoxicates the present. Its opposite extreme is not represented by the high-brow but by all that which is simply mediocre (Greenberg 1939; Dorfles 1972).

Kitsch is to inauthenticity as art is to authenticity, even while maintaining the fact that not even “great art” can entirely lack **bad taste** precisely because every form of art contains “a minimum of convention, of the acceptance of pleasing the client, from which no artist is immune” (Moles 1971). Even today the hyper-production of **kitsch** can be seen as a response to the uneasiness of the common man or, in Moles’ terms, to “the inability

of the average conscience, of the man of the masses, to raise himself up, other than by gradual steps, to the heights of man's philosophy, industry and products, and to accept them as such" (Moles 1971).

Reception

To view or receive means to enjoy or not enjoy something and thus to find pleasure or displeasure in it; it also means to **taste**, listen or to allow oneself to be taken over by an **emotion**. Experiences, whether or high or low levels of involvement, imply two levels of investigation: a first, immediate moment of experience (tasting, for example) and a second that reflects on this experience, and which in some way also creates distance from the object in question (an analysis about that which one has tasted, which often then leads to a judgment: "I like it" or "I do not like it").

Our daily experience is filled with judgments of **taste** cloaked in **consciousness**: "this is beautiful", "that one's ugly." Due to the ease with which we issue judgments, we are not aware of its complexity. We are not aware of how much that judgment depends on our history, our culture, our educational backgrounds, the society in which we live, on the visual, palatal or sonic **taste** in which we are immersed, on subjective inhibitions, openings, and closures in relation to new experiences.

If we want to recall some of the issues that **taste** raises, we should first ask ourselves if there is only subjective **taste** or if it is possible to speak of a norm or a rule for **taste**. If we establish that we can speak of such a rule, we must then ask if it has any normative or regulative value; i.e., if **taste** is a question of immediacy or if it derives from a thought that meditates on and recognizes an object with a specific quality; and whether anyone is able to make a judgment or if this is only the privilege of the critic.

In the **eighteenth century** the need was felt to have a definition of **taste**. The century also saw the development of the "critic" (and the birth of the role of the art critic) who represents the "institutional" side of reception. At the basis of the eighteenth-century investigation we find the

broadly shared presupposition according to which – even if strongly compromised by sense (sight, hearing, touch, **taste**, smell) – pleasure is shared; sharing thus becomes the basis for a common sense. **Taste** seems to be a unity of individual preferences that nevertheless coalesce and coagulate within a community that recognizes them (Du Bos 1719). This claim to universality seems to stand in contradiction with an entirely subjective system of choice. The normative nature of the **Enlightenment** reflection on taste revealed in the writings of German authors has a historic origin in the relation to the precepts of good **taste** in seventeenth-century France, as well as conceptual roots in the shift from the use of the term "**taste**" in its physiological dimension to a figurative, intellectual use. The notion of **taste** is in fact characterized by a normative value both within its physiological version as well as in a theoretical, cognitive sense. The basic question for the normative **nature of taste** is represented by the study of those elements that might make up such norms (the faculty of the soul, of the imagination, intellect, reason; their functioning, the definition of the parameters of a correct faculty of judgment) and by the problem of the normative effectiveness of **good taste** and the role of elements considered as composing it (Hume 1757; Kant 1790; Mazzocut-Mis 2012).

Through the multiplication of artistic languages over the twentieth century, **taste** was no longer able to pose itself as a unitary point of reference. Many avant-gardes (and neo-avant-gardes) push against any exercise in **taste** that attempts to center itself as an inter-subjective **aesthetic judgment**, opening themselves up instead to the two polarities excluded by eighteenth-century judgment: the physiological – e.g., the artistic field that stimulates visceral reactions in the spectator: the ugly, the **sublime** and disgust (Menninghaus 2003) – and the more specifically intellectual – e.g., the horizon of conceptual art or the ready-made (Danto 2003). The removal of technique as a point of convergence for **taste** – the value of a work inasmuch as a product of manufacture is no longer an element under judgment – has slowly diminished the claim to universality from a critical-evaluative point of view.

There is, however, still another aspect to be analyzed. Over the last 50 years, the problem of **reception** has broadened our investigating psychological, sociological, physiological, and neurological horizons. The artistic universe thus becomes one of **emotions** that can even be measured and validated from a psychological, psychiatric, or neurological point of view. Furthermore, Aesthetics must now face the disciplinary challenges established by neuro-aesthetics, using its own conceptual tools to shed light on the implicit and unexplored claims of these disciplines without, nevertheless, being passively assimilated into new cultural horizons. Over the 1980s, Aesthetics has opened up to neuro-scientific research distinguished by the discovery of mirror neurons, a particular class of visual-motor neuron situated in the ventral premotor cortex (area F5) and in the inferior parietal lobule of macaques and humans alike, which has been attributed with the development of information relating to the comportment of others. Mirror neurons activate when we look at static images of actions or **emotions** and even representations of objects of still lives, which stimulate the mechanism of motor simulation, inducing the viewer to act *as if* the image represented was effectively real. The success of this discovery has not, nevertheless, radically transformed research into the role of the viewer, inasmuch as while it is true that the active cerebral zones that allow us to appreciate a Picasso painting, these are the very same that allow us to look at any kind of colored object. The question about why and how we judge something to be beautiful, ugly, **sublime** or **kitsch**, etc. remains (Chatterjee and Vartanian 2016; Leder 2013).

What is the future of **taste**? This depends on the constantly evolving object that is the **work of art**. If it is true that it is no longer necessarily **taste** that dictates the rules of art, it is also true that art requires a public that dictates its rules, rules that can be maintained or ignored. They are maintained if there is a meeting with the masses (as in **kitsch**) or ignored if the public is not the main horizon of reference, as has been the case for avant-gardes.

In order to understand tomorrow's viewer, we must thus also wait for the art of the future, a form

of art that will move within reproduction, stereotyping and, perhaps, the development of new technologies, and within the unique, unrepeatable character of the **here and now**. Perhaps in the near future even the method of reception will radically change. That which probably will not change is the method of expressing judgments of **taste**, whether more profound and reflective or superficial and entirely a-temporal.

Creation

When one speaks about “creativity,” even if the usual use of the word might seem well defined, one needs to bear in mind that we are dealing with an expression that has changed its meaning over the course of the centuries. It is a term that did not appear in philosophy, theology or European art for nearly a 1000 years: the Greeks had no corresponding term; the Romans did, but they did not apply it to any of these three fields.

What is creativity then, and what is its connection to possibility?

Speaking about “**genius**” means, first and foremost, referring to an expressive field that, beyond the aesthetic history of the concept, refers to subjective abilities made explicit in the production of artistic objects. These abilities have, in various ways, intersected with those of **taste** that sometimes are inseparable from them. The bond between **genius** and the subject's inventive immersion can be seen through different pathways which do not always coincide, ranging from **rhetoric** to psychology and from poetry to theories of expression.

It was yet again in the eighteenth century, as was the case with **taste**, that the need was felt to conceptually define **genius**, beginning from its poetic-rhetorical roots (Batteux 1747; Du Bos 1719). The artist (or, better still, the **genius**) interprets, develops and constructs through their confrontation with nature – in which they themselves are rooted. The interpreter's vision is, or ought to be, impersonal, and contains an attempt to put subjective daily passions between brackets in order to open a direct and universal relation between perspective and the world. In this relation (which is in itself representation), the “possible” is

formed, which is the artist's own choice. The artist interprets nature, creating a "new nature", which is itself the work of art (Gerard 1774). **Genius** is thus not an unregulated power, but rather the natural talent that gives art rules, constructing "**aesthetic ideas**" capable of animating the complexity of all subjective faculties (Kant 1790). This complexity – and perhaps here we find the aporetic conclusion of the entire journey of eighteenth-century aesthetic thought – which can no longer be contained within a harmonious and regular framework.

Over the nineteenth century, the power of creativity widened out and **genius** was the flame that fired up artists to rise up; one can clearly see a changing relation between **genius** and **taste** which, in the century of **Enlightenment**, saw the second of the two terms take the dominant position. In the nineteenth century there were differences of degree between the two principles but not qualitative differences, because one can say that **genius** became independent of **taste**. This shift raises the question of whether **genius** contains **taste** within it or whether **taste** ought to be understood as already **genius** in itself. Both of these two directions, however, seem to claim the assimilation of **taste** by **genius**, meaning that in the nineteenth century **genius** was decreed as omnipotent (Schelling 1796–1805; Hegel 1835).

Today we no longer talk about **genius**, and we can only speak about "**creation**" with difficulty. The artist does not necessarily create **works of art** (as much as the artist seems to be situated within this expression with a certain durability or even permanence) but instead builds, develops or simply presents objects that enter into a circuit call the **art market**. The twentieth century seems to have definitively removed the notion of **genius** from the divine, **mythical aura** to which it was still attributed in the nineteenth century. Many artists even began to claim the impersonal dimension of their authorial status. It is almost as if, after centuries of productive effort to be recognized in their own right, the parabola of **genius** has to be drawn back into its work or by a kind of factory stamp more similar to a brand than an artist's signature.

What is the status of the creator today, and what is a **work of art**? One used to say that the

artist creates self-sufficient "beings", from which arise perceptions and affects that are cannot necessarily be assimilated to those of their creator. But of how many objects entering into the **art market** today are we prepared to attribute the preceding definition?

We know that Duchamp did not present his *Fontaine* (1917) for artistic delight but that, soliciting a reaction against visual indifference, hoped to reawaken people from an aesthetic slumber. Phenomena of aestheticization of daily life within the artistic sphere seem to have stimulated a reflection both on the **here and now** (society in its commonly accepted forms, its canonized deformities, its preconceptions, etc.) as well as on the medium that expresses it (art itself). But can this "magic" continue indefinitely? The reification of the daily object within the museum circuit and that of the **art market** makes such objects open to being bought and sold, increasing their economic value. Faced with a reified object of this kind, it is difficult to question George Dickie's definition according to which it is the art world – i.e., its experts – who determine what art is (Dickie 1974): a definition that is not entirely outdated and which holds true in many spheres.

In the twentieth century, while many avant-gardes opposed the standardization and commodification of art, arguing against bourgeois and **kitsch taste**, at the same time the art market and the entertainment industry made art its own product, a mass experience, a brand.

It is thus difficult today to answer the question about what the status of the creator might be. We are in a period of fast, unstoppable change. Nevertheless, something remains and is conserved. A vast horizon lies ahead of us waiting to be investigated, in which creativity and **reception** meet and fall away, love and hate each other, looking to each other for commercial goals or meeting simply on the basis of the unfathomable basis that is emotion itself.

Conclusions

Let us take a last look at Duchamp, who in 1914 made an artwork out of a bottle-rack.

This involved no more than a simple syntactical maneuver – from the cellar to the museum; this is *de facto* a semantic shift, from an instrumental object to an art object. The world thus opened up, as it has done, to every possibility. Since then art and the possible have been held in an inextricable and complex tension that has led to radical changes in which we are still immersed. In a certain sense, the **ready made** led the way to the hyper-realism that has today become, more than ever before, a dominant theme in the recognition that new technologies have had, and continue to have, over the field of **creation**. **Ready made** has now become, as Baudrillard underscores, the “virtual technology media circus” and the “perpetual **reality** show” (Baudrillard 1995). Art invades **reality** and **reality** invades art, removing Aesthetics, which investigates **creation** and reception. From every comfort zone provided by the discipline’s history. When the image of **reality** coincides with **reality** itself, or when the **art work**, in coinciding with an instrumental object, becomes an artistic object only by inserting itself into the museum circuit and that of the **art market**, then Aesthetics must change its standpoint and, without nevertheless losing itself, turn to other disciplines. In the end, new technologies – marked by immersion and the increasing involvement of the receiver, the viewer – open up new challenges, chasing the new dream of a **reality** that increasingly confuses itself with the virtual and vice versa.

Abstract

Affordances have been conceptualized by J. J. Gibson as what the environment offers, provides or furnishes the organism, in other words, as possibilities for action. However, this notion is not without controversy, in particular surrounding its nature and properties. This entry will consider the ways in which the concept of affordance can help us build a material theory of the possible, one that is intimately related to both subjective experience and to culture. The entry discusses different definitions of affordance, its types and characteristics, before outlining a model of the possible based on the interplay between materiality, intentionality, and normativity. The implications of this model for our understanding of agency and possibility are discussed in the end.

Keywords

Affordance · Materiality · Intentionality ·
Culture · Objects · Agency

Introduction

Chairs are typically made to sit on. Glasses and bottles help us store all sorts of liquids. Mobile phones allow us to call or text people. A boat is meant to float on water. In each one of these cases, what I am referring to are key affordances. Chairs afford sitting, glasses and bottles afford drinking from, mobile phones afford communicating, and boats afford sailing. That is, in principle, what they do. A boat with a hole in it loses its affordance of floating. Similarly, a broken

glass cannot carry liquid or can carry much less of it. At the same time, all these objects afford much more to our action than singular possibilities, for as convenient (and conventional) as these possibilities are. One can also stand on a chair to reach something on the top shelf. Or can use a mobile phone to play music or watch videos.

As we can see from the brief discussion above, there is something intrinsically important about the relation between affordances, action, and possibility (as well as **impossibility**). Affordances facilitate, guide, constrain, and sometimes forbid specific courses of action. At the same time, they are multiple, dynamic, and relational. As I will discuss further in this entry, an affordance is not a universal property of an object. Chairs don't afford sitting for everyone at all times; for example, they would be too tall for toddlers to reach and adults in a pitch-dark room would never realize they are even there – either way, affordances represent a *meeting point* between person and environment and reside in neither of them.

The notion of affordance was coined by James J. Gibson, a founding figure of ecological psychology, the branch of psychology focused on the importance of the environment for human perception and action. Of course, the interest in the environment and its objects precedes Gibson and yet it is his notion of affordance that became very popular and started being used in a variety of applied fields (Luyat 2009). This popularity ignited also many controversies – several of which will be reviewed here – that make the concept difficult to grasp, conceptually shift, and either too wide or too narrow to be used in practice. It is worth noting here that Gibson himself didn't propose a full theory of affordances and merely got a chance to sketch this notion, often in contradictory ways. His interest was mainly in the study of perception, in particular visual perception (see Gibson 1986). Gibson believed that, when we perceive objects, we don't merely form a mental representation of their sensorial properties or qualities but what we perceive are their affordances, i.e., what they afford our action. In this way, he considered perception as an activity.

It is this close connection between affordances and human activity that prompts many scholars to define the former as *possibilities for action* (see Shaw et al. 2019). This proposition has been studied mainly from the point of view of action but what exactly does “possibility” mean here? And how can affordances help us build a material theory of the **possible**? The present entry focuses on these two questions. In order to answer them properly, however, we need to understand better what an affordance is, why it can be hard to theorize, and what its characteristics and types might be.

Definition and Controversy

Gibson famously defined affordances in the following terms:

The affordances of the environment are what it offers the animal, what it provides or furnishes, either for good or ill. The verb to afford is found in the dictionary, but the noun affordance is not. I have made it up. I mean by it something that refers to both the environment and the animal in a way that no existing term does. It implies the complementarity of the animal and the environment. (Gibson 1986, p. 127)

The idea of complementarity between animal and environment, mentioned above, is essential to understand Gibson’s thinking and his overall project of overcoming mind-matter and mind-body dualisms. The study of perception before him often pitched an external, objective reality against the personal and subjective ways of making sense of it. For Gibson, an affordance “points two ways, to the environment and to the observer” (p. 141). It is, as such, a relational notion, one that cannot and should not be attributed to either environment or observer but their interrelation. Greeno (1994) considered this interrelation as the articulation between affordances or attributes of something in the environment and the abilities (or effectiveness, or aptitudes) of the person. The presence of both is necessary for action or for actualizing an affordance. However, this formulation risks throwing the notion back into old dualisms between person and world. By firmly linking affordances with material attributes, some might

be tempted to study them separately from the abilities of the person. We can imagine, for instance, listing material affordances in abstract terms, independent of any individual abilities. This falls short of Gibson’s plea to refer “both” to environment and animal, for affordances to be “equally a fact of the environment and a fact of behavior”, “both physical and psychological, yet neither” (Gibson 1986, p. 129).

Another well-known reinterpretation of the notion of affordance comes from Donald A. Norman who made them popular in design studies. For him, “the term affordance refers to the perceived and actual properties of the thing, primarily those fundamental properties that determine just how the thing could possibly be used” (Norman 1988, p. 9). From a designer’s perspective, it makes perfect sense to focus on perceived affordances and how easy or hard it is for users, for example, to pick up the fact that a possibility for action exists and can be acted upon. “When affordances are taken advantage of, the user knows what to do just by looking: no picture, label or instruction is required” (p. 9). But here, once again, we enter the same old problem of dualism. By distinguishing between “real” and “perceived” affordances, Norman as well accepts that an affordance can exist in objective terms without an observer to “meet” it and, in “meeting” it, to make it possible. Gibson himself was tempted by the idea of affordances as objective features before rejecting it based on his anti-dualistic stance: “the affordances of the environment (. . .) are in a sense objective, real, and physical, unlike values and meanings, which are often supposed to be subjective, phenomenal, and mental. But actually, an affordance is neither an objective property nor a subjective property; or it is both if you like” (Gibson 1986, p. 129).

The difficulty of studying affordance as a truly relational phenomenon has plagued this area of research for more than four decades and it continues to do so today (see, for instance, the recent distinction between physical and neurocognitive levels in Osiurak et al. 2017). This has made many scholars highly critical of the term and its use (e.g., Oliver 2005). And, in fact, the roots of this discontent can be found in Gibson’s own writing

and his own failure to overcome dualism. Consider the following passage:

The concept of affordance is derived from these concepts of valence, invitation, and demand but with a crucial difference. The affordance of something does not change as the need of the observer changes. The observer may or may not perceive or attend to the affordance, according to his needs, but the affordance, being invariant, is always there to be perceived. An affordance is not bestowed upon an object by a need of an observer and his act of perceiving it. The object offers what it does because it is what it is. (Gibson 1986, pp. 138–139)

Here Gibson lays the ground for the hypothesis of *direct perception* of affordances, in other words their objective reality, outside the observer, and their immediate grasp whenever “information is available in ambient light for perceiving them” (p. 140). Not only does this claim betray anti-dualism, but it also ignores the basic fact that our interaction with the material world is thoroughly cultural and grounded in acts of learning with and from others. In the words of Dant (1999), the “material environment is not natural or given” (p. 12) and our “interactions with things – touching, making, looking at, talking and reading about, using, storing, maintaining, remaking and so on – are social in that they are learnt and shared within the culture” (p. 14). To come back to the initial example of the mobile phone affording making calls and listening to music, these affordances would never be spotted through direct, culturally unmediated perception. One needs to have learnt about phones in order to perceive these affordances even “in ambient light”.

Gibson was well aware of this critique and, at different points in his writing, formulated it himself (see, for example, his discussion of mailboxes). As he noted, direct perception often reveals affordances but not always. “We must, of course, learn to see what things really are – for example, that the innocent-looking leaf is really a nettle or that the helpful-sounding politician is really a demagogue. And this can be really difficult” (Gibson 1986, p. 142). Once more, affordances do not “belong” to material reality alone; they are emerging from the co-evolution of person and environment that is culture. Costall (1995, p. 472) added

to this discussion when he rightfully claimed that learning affordances doesn’t simply concern what they happen to afford but what they are *meant* to afford. Culture doesn’t only make certain affordances obvious to us – like sitting on chairs and drinking from glasses –, it creates conventional or canonical uses that are hard to think beyond. Could chairs be glued to the wall and be called art? Yes, their material structure affords this action, but we need some special person attributes to enact it. And this has major consequences for what is possible.

Last but not least, there are some other controversies associated with the definition and description of affordances. For instance, it is debatable whether they are stable and permanent or fleeting and highly situational. Gibson’s writing seems to suggest both even if he often argued for the former. Chemero and Turvey (2007, p. 33) disagree: “affordances are exquisitely context-dependent and ‘quicksilvery’: they emerge and dissolve very rapidly, due to small changes in the animal, environment or both.” Once more, we are coming back to the objective (and thus invariant) versus relational (and thus situational) nature of affordances. In this entry, I will strongly argue for the latter, in agreement with the spirit of Gibson’s anti-dualistic stance, even if not always in line with his actual statements about affordances. The fact that an affordance is, indeed, relational, plays an important role in how we theorize the possibilities associated with acting on affordances. Before outlining this in more detail, let’s consider the characteristics and types of affordances, a discussion that prepares the ground for the framework of the possible proposed at the end.

Characterization and Types

Following Gibson, there are three main characteristics of an affordance:

1. An affordance exists relative to the action capabilities of a particular actor.
2. The existence of an affordance is independent of the actor’s ability to perceive it.

3. An affordance does not change as the needs and goals of the actor change. (McGrenere and Ho 2000, 1)

These are all derived from his definition of affordances as relational, person-environment phenomena, but also reflect Gibson's belief in the somewhat "objective" nature of an affordance. On the other hand, as we have also seen before, authors like Norman would argue that the most important characteristic of an affordance rests in how easy it is perceived, and this depends on the person's knowledge, experience, and culture (p. 3).

How can affordances be both relatively stable and "objective" as well as highly flexible and situational? This point of debate, raised in the previous section, is addressed by a simple typology proposed by Shaw et al. (2019) who distinguished between *affordance-types* and *affordance-tokens*. The main distinction here concerns the level of generality or abstraction. For instance, in general terms, all chairs afford sitting. This is an affordance-type. But any particular chair might not afford sitting for a particular person either because of the stability of the chair, weight of the person, or maybe because someone else is already sitting on it. In these cases, the affordance-token is missing. There is, of course, a deep connection between the two. In the words of the authors, "epistemologically speaking, types can be known only through their tokens, and the collective resemblance the tokens share is the type" (p. 5). In the end, it is a matter of scale dependency – for affordance-tokens – and independency – for affordance-types.

This distinction helps us rethink the issue of generality and specificity, but it tells us little about the "content" of an affordance and its exact relation to action. Given that human action is different from simple behavior and it has a deeply social and cultural dynamic, affordances can once more be read at different levels depending on the aspects of the action we are focusing on. Pols (2012) differentiated in this regard between *basic actions* (e.g., sitting on a chair), *the consequences of these actions* (e.g., the fact that another person cannot sit there at the same time), *the coordination of actions into a*

plan (e.g., coming early to make sure you have a seat), and their *broader social impact* (e.g., sometimes the simple act of sitting has political implications, for instance Rosa Parks' refusal to give up her seat to a white passenger and its role in the civil rights movement). Hence, the act of sitting affords many more things, individually and socially, than resting on a chair and this needs to be recognized. Affordances can thus be understood hierarchically as affording basic actions, affording the effects of those actions, affording the execution of plans and, at times, affording social action as well. The higher we go up this "ladder," the more the hypothesis of direct perception fades and leaves room for a cultural view of what an affordance is.

Another typology, proposed by Gaver (1991), focuses on the relation between the presence or absence of an affordance and the presence or absence of the perceptual information that exposes it. This distinction between "real" and "perceived" resonates widely with Norman's understanding of the term and, when put together into a two by two table, generates four possibilities: *perceptible affordances* (present and perceived as such), *hidden affordances* (present but not perceived or perceived as absent), *false affordances* (absent but perceived as present) and *correctly rejected affordances* (absent and perceived as such). Putting aside the dualistic underpinning of this framework and the fact that it undermines the relational nature of affordances, it does raise the interesting practical question – for designers and not only – of how people can be helped to discover more of the hidden affordances of things and avoid false ones. Added to this is the question of how ready a person is to actualize or enact an affordance once it is perceived. Because we can easily imagine situations, for instance, in which the affordance of making calls with a mobile phone is clearly perceived but, given that the phone belongs to some else, this affordance cannot really be acted upon. In this regard, Anderson and Robey (2017) introduced the notion of *affordance potency* designating "the strength of the relationship between the abilities of the individual and the features of the system at the time

of actualization, conditioned by the characteristics of the work environment” (p. 103). We return here to the original Gibsonian idea that affordances will depend equally on the “match” between animal and environment.

But we also return to the role of culture and the fact that canonical uses of objects always have a higher affordance potency, i.e., they are much easier to actualize. Thus, chairs are perfectly made for sitting but make it difficult for someone to sleep in them comfortably. There is, as such, a normative aspect to the perception and use of affordances, just as there is a personal element of goals and needs motivating human action. Based on all these three elements – intentional, norms, and affordances – our action in the world can be either more conventional or more creative/surprising. How do we use affordances for creative action? I proposed in the past a small typology (see Glăveanu 2012) distinguishing between *unperceived affordances*, *uninvented affordances*, and *unexploited affordances*. Creative people tap into one or more of these categories in order to go beyond the conventional of their and others’ existence. They do so by becoming aware of new affordances in their environment (e.g., a glass can be used to hold down paper on a windy day), inventing objects with new properties whenever needed (e.g., glasses can be piled up together to create a building in children’s play) and, sometimes, going against cultural norms in order to expand the possible (e.g., glasses can be broken to generate pieces with new affordances).

Towards a Material Theory of the Possible

It is no coincidence to mention **creativity** in a discussion of affordances. In fact, as Gibson noted from early on:

The fact that a stone is a missile does not imply that it cannot be other things as well. It can be a paperweight, a bookend, a hammer, or a pendulum bob. It can be piled on another rock to make a cairn or a stone wall. These affordances are all consistent with one another. The differences between them are not clear-cut, and the arbitrary names by which they are called do not count for perception. (Gibson 1986, p. 134)

With this statement, he demonstrates the use of divergent thinking when it comes to a stone, an exercise that strongly reminds us of the Unusual Uses task developed by Guilford (see Goldman 1965), asking respondents how many things they could do with a brick. If affordances designate action possibilities or action potentials, as I called them in the past (see Glăveanu 2018), then the creative process can be defined as an active exploration of more of these possibilities than what is conventional or canonical (Glăveanu 2012). In the end, **change** is ubiquitous when it comes to affordances, something aptly captured by Heft who said that, “from the perspective of sociocultural change, new entities with novel affordances are introduced into the culture, new affordances of familiar objects are realized, familiar affordances are sustained over time through continued use, and affordances fade from the scene through disuse” (Heft 2003, pp. 175–176).

What does this have to do with the possible? Not only is creativity one of the key processes involved in engaging with the possible, but my argument here is that a closer consideration of affordances can hold the key to developing a material theory of human possibility. I call it “material” in order to emphasize the close link between affordances and the material properties of objects without conflating the two. Indeed, as stated before, in a non-dualist, sociocultural framework, affordances *cannot* be separated from the person and located strictly within the environment. Nonetheless, this notion highlights the fact that physical properties do exist and they do matter, enormously in fact, for what we perceive as possible and what we enact of it. Affordances bridge material properties and the person’s intentions and abilities seen as an inseparable whole. They are at once material, psychological, and cultural, helping us overcome the historical difficulty of considering culture in non-reductionist ways (as either material only or primarily non-material; Reckwitz 2002).

The seeds of the possible can be found in the interest to understand how exactly affordances become actualized. More specifically, how we move from “possibility-for-action to actuality” (Shaw et al. 2019, p. 12) and, I would add, the

other way around: how actualized action opens up a new horizon of possibilities. My argument, building on a model I proposed a few years ago (see Glăveanu 2016), is that a reflection on affordances and their relation to materiality necessarily invites a closer consideration of intentions or **perspective**, on the one hand, and norms and culture, on the other.

To take a concrete example, let's go back to the idea of sitting on a chair. As we have established, there are many things that are possible in terms of our action with chairs or, using the vocabulary here, many affordances that could be actualized. What we often actualize from them though is the rather conventional option of taking a seat. This is what we typically intend to do when looking around for a chair in a crowded room, and also how we are culturally encouraged to behave (in other words, nobody in the room would be shocked if we take a seat, unless perhaps if we bypass an elderly person or a pregnant woman). Still, there is more – much more – to the horizon of the possible in using chairs. To explore the possible further we would need to examine the gaps or tensions between what we *could do* with a chair (the material aspect captured by affordances), what we *would do* with it (the psychological aspect captured by intentions or perspectives), and what we *should do* with it (the cultural aspect captured by norms and normativity). What might be possible if we change the material properties of a chair by modifying its shape, size, color, etc.? What about if we were approach it with another intention than sitting, what else could we want from it? Finally, what kind of cultural norms are there around the use of chairs and how do they vary? What would it mean to violate them?

All of these questions test the limits of what is possible and invite us to consider different “categories” of affordances. Those that expand our perspective on the world and tap into previously unperceived possibilities. Those that modify the material support and its attributes, resulting in new, “invented” artifacts. And those that contradict one or more cultural norms in order to enlarge the space of what is possible in a given situation, thus enacting unexploited alternatives. And then

there are uses that enact more than one of these possibility-expanding actions at once.

Reading the possible in terms of the dynamic between *materiality (could)* – *intentionality (would)* – *normativity (should)* relies thus heavily on a series of relational concepts such as affordance (the meeting point between “could” and “would,” shaped by culture’s “should”) and perspective (the “would” of our actions that meets the “could” and the “should” of the material and the social world, respectively). If affordances are action potentials, perspectives are action orientations that come to discover and use these potentials (see Glăveanu 2018). But affordances themselves can shape perspectives, something nicely emphasized by Withagen et al. (2012) when they argued that affordances also invite behavior. Going back to the chair example, sometimes the mere sight of it and its affordances makes us aware of how tired we are and in need of a seat.

Summary

This entry defined affordances from multiple perspectives and covered some of the main controversies around this old concept. It reviewed different typologies of affordances that complexify the notion and make it a better fit for the study of complex human action. The possible represents such a highly complex phenomenon and, in its exploration, we need to consider affordances and materiality in their relation to personal attributes and with culture. The interdependence between materiality – intentionality – normativity and the ways in which affordances both enable and constrain our possibilities for action are at the heart of the possible and of human **agency**. Agency itself, when it comes to exploring what is possible, doesn't reside in the person or in the environment alone, but in their interrelation. It is thus best defined as *co-agency* (see Glăveanu 2015) and studied in the interplay between action orientations (perspectives) and action potentials (affordances), both within a sociocultural frame. Gibson wrote that “the possibilities

of the environment and the way of life of the animal go together inseparably” and that, “within limits, the human animal can alter the affordances of the environment but is still the creature of his or her situation” (Gibson 1986, p. 143). Expanding these limits is the province of the possible and a direct consequence of the state of co-agency that defines human existence.

Abstract

Also known as “hermetic science” in reference to the writings of Hermes Trismegistus, Alchemy is a type of knowledge that has developed over the centuries based on the interactions between mysticism, science, and art. Although not considered a natural science like today's chemistry, physics, biology, among others, Alchemy still permeates human thought, in a way that references can be found in several cultural manifestations. Thus, the objective of the present entry is to discuss the idea of the possible on the threshold between these two perspectives: Alchemy and

Chemistry, with special attention to the relationship between science, mysticism, and art. For this, we explore the question of the possible from an analysis of the processes of signification of some alchemical representations, observing how such knowledge could have unfolded in what we know today as Chemistry, with particular attention to the concept of fusion, which is understood in Alchemy as a process of joining bodies through the purifying power of fire, and, in Chemistry, as a change in physical state or a type of junction of melting metals to form alloys.

Keywords

Alchemy · The possible · Chemistry · Semiotic · Science

Introduction

Magic, secrets, and mysticism. Alchemy still holds the public attention to this day. On the one hand, this is due to the success of literary/cinematographic works (such as the “Harry Potter” saga) that broaden people’s horizons with ideas inspired or similar to Alchemy (Martinon-Torres 2011). On the other hand, the recurring association between alchemical practices and esotericism, mysticism, occultism, and religiosity keep this ancient tradition alive in the practices of occult groups until today (*Ibid.*). Thus, what would Alchemy be in such a context? How could we define it?

According to Principe (2013), this has been one of the most intricate issues for historians of science for a long time and for a variety of reasons, from which two are worth mentioning here: the scarcity of historical sources, especially from the medieval period, which allowed greater assertiveness about what was done in alchemical laboratories and with what intentions; and the several errors or excessive simplifications – from a historiographical point of view – that ended up erasing important details of history. However, advances in the historiography of Alchemy ultimately added another perspective on this subject (Newman and Principe 1998).

For Nummedal (2016, p. 59), Alchemy comprises a “surprisingly cohesive intellectual tradition stretching from Greco-Roman Egypt, where alchemy seems to have originated, to the present.” Not only does Alchemy comprise the literature on this tradition, but it also includes a set of practices, ways of doing and thinking that characterize, more or less, the so-called Great Art. According to Perez Pariente (2016), the *Papyrus Leiden I (Ipuwer Papyrus)*, for example, which dates from the third century, depicts a description of procedures to obtain metallic alloys that mimic the appearance of gold and silver, to form substances with the appearance of gems, as well as information on dyeing fabrics. Still, according to the author (Perez Pariente 2016), several more or less perennial characteristics can be observed throughout the extensive alchemical tradition, such as: the use of symbolic, allegorical, and sometimes hermetic language, both to express deeds, as well as to hide them; vitalism, that is, the constant comparison between the processes of evolution of matter and those in living organisms; and the belief in the existence of an evolutionary line of metals, ranging from the most common metals such as iron and lead, to the most perfect metals, such as silver and gold – which would explain the resistance of gold to various chemical reagents, for example. Finally, we note that there is an influence of the Aristotelian doctrine on explanations about the constitution of matter – notably the theory of the four elements, originally proposed by Empedocles (c. 490 BC – 430 BC), but adopted and propagated by Aristotle (Kingsley and Parry 2020) – and elements of magic and mysticism that are commonly associated with alchemical tradition.

Anyway, when it comes to Alchemy, it is undeniable that there are records with very suggestive language, rich in allegories and word games, which came in handy during movements from different spheres of human culture, such as Romantic poetry, German idealism, and modern literature (Roob 2003). In several texts, there is frequent mention and use of explanations based on worldviews close to mysticism, as they resorted to arguments such as astral magic, gods, spirits, cosmic souls, from Gnosticism to Kabbalah (*Ibid.*). Therefore, as detected in some works

on historiography of Alchemy, such as the propositions of Newman and Principe (1998) that emphasize more material aspects and that blur the boundaries between chemistry and alchemy. Although historiographically well-founded, these are still a topic of discussion, as Pérez Pariente (2015) also points out.

Contrasting this description of Alchemy with the scientific practices that today characterize Chemistry, it is possible to observe a non-negligible overlap with regard to instruments, techniques, ideas, and proto-ideas between the two practices. However, these traditions are reasonably different from each other. Considering this, an intriguing question is: How was this historical change possible, from a “science” like Alchemy, based on mysticism and religiosity, to today’s chemical knowledge? How can Chemistry, Alchemy, and the processes of signification between both traditions be analyzed in order to understand the possible under these two perspectives?

Based on this overview, the objective of this entry is to discuss the idea of the possible on the threshold between Alchemy and Chemistry, with special attention to the interactions between science, mysticism, and art. Thus, the possible is considered as something that emerges in the encounter between two perspectives, as pointed out by Glăveanu (2020), and not just as a product that opposes what is real or concrete. Therefore, when analyzing the transition from Alchemy to Chemistry, it is assumed that this comes from the emergence of a novelty (see section Novelty) (Brioschi 2020), in the process of signification, through semiotic mediation. Based on this idea, this entry adopts the model $A \leftrightarrow \text{non-}A$ (Valsiner 1998) to understand the processes of signification through mediation by signs, following the semiotic perspective (see section Semiotics) (Innis 2020). For this, the question of the possible is explored from the analysis of the processes of signification for two images (iconic and metaphorical) associated with alchemical practice, and how this knowledge may have unfolded later in what Chemistry calls a fusion process – a change of state of matter or the “combination” of melting metals.

The Possible in Alchemy: From Alchemy to Chemistry

In the work of Martinon-Torres (2011), the idea that a direct association of several mystical, occult characteristics corresponded to Alchemy as a whole is contested, and its further departure from Chemistry is assessed. At first such a description of Alchemy – often in a derogatory tone, as pointed out by Principe (2011) and Newman and Principe (1998) – led to the defense that Chemistry emerged as a breakdown with an archaic, irrational, and fraudulent knowledge towards a modern, scientific, and rational knowledge. Later on, according to Marie Boas Hall and other historians of her generation (Newman and Principe 1998), these ideas have been revisited, giving rise to a multiplicity of interpretations and hybridizations between Chemistry and Alchemy especially in the period between the sixteenth century and the end of seventeenth century. If this makes the problem of Chemistry boundaries between Alchemy somewhat thorny to be analyzed, it nonetheless multiplies the possible interpretations of the processes of signification at the threshold between these two traditions, as will be explored throughout this entry from the “ground” of the possible.

A reinterpretation of the transition from Alchemy to Chemistry starts from some assumptions, among which we highlight that to assert a clear distinction between Alchemy and the emerging Chemistry before the eighteenth century implies to say that the authors of that time already did it in their writings, which is false. It is possible to observe authors who used both terms interchangeably (Alchemy and Chemistry) to refer to their own practice (Martinon-Torres 2011). An example of this is in the book *Alchemia* (1597), written by Andreas Libavius (1550–1616). The book states that *chrysopoeia* (gold-making) is established under the aegis of Chemistry, although it resorts to rather alchemical concepts, such as the very idea of producing gold from “inferior metals” (the transmutation). Another important assumption to be mentioned concerns the etymological reconstruction in both words. According

to Newman and Principe (1998), such interpretations about the origin of both the words Chemistry and Alchemy were replicated in textbooks and encyclopedias, often attributing the *chrysopoeia* exclusively to Alchemy, which created the false impression that such a distinction was already well established in the sixteenth and seventeenth centuries.

To address this anachronism, Newman and Principe (1998) suggest the use of the archaic term *chymistry* to refer to this hybrid discipline dated from the sixteenth century to the end of the seventeenth century. Before that period, the use of the term chemistry was rather insignificant, but then, after the end of the seventeenth century, Alchemy started to wear off. For the authors, the use of *chymistry* in this case does not directly evoke Alchemy or Chemistry (Martinon-Torres 2011). Thus, the creation of the concept of *chymistry*, as something that is between Alchemy and Chemistry, can be considered as a reflection of how the possible emerges out of the relations of tension between two perspectives, in this case, two fields of knowledge.

Alchemy: Science, Mysticism, and Art

As explored briefly, Alchemy relates to mysticism and the arts. In addition, it also relates with what came to be known later as modern science. Starting with the last, we can point out some intersections between Alchemy and modern science. The first, more direct, concerns the period in which it became known as *chymistry*, as discussed earlier. In this period, the Great Art was often indistinguishable from the emerging chemistry, so that they share practices and theories – both techniques that chemistry ended up inheriting in its daily practice, as well as ideas and proto-ideas that were later further developed in the course of the development of the chemistry (Martinon-Torres 2011). As some examples, it is possible to mention the distillation processes, sometimes attributed to Cleopatra the Alchemist (fl. c. third century AD), and a variety of instruments and techniques, linked to the artisanal knowledge of many alchemists, like the *bain-marie*, which

would have been created by Mary the Jewess (c. first to third century AD). All these instruments and techniques represent how the manipulation of materials were understood with the goal to modify the nature. In this sense, the new (construction) emerge from the old (destruction), in which the alchemist played an important role of intervening in the transformations of nature. It represents a metonymy of the tension between change and permanence that permeates the core of this entry, as examples of the dynamic $A \leftrightarrow \text{non-}A$ of meanings that will be more developed further up.

As for mysticism and art, the references of alchemical writings to divine entities and mythologies, sometimes created on their own, were constant. With regard to the mysticism present in Alchemy, Roob (2003) points out the evidence of mysticism especially associated with the use of allegorical language – fruitful in possibilities of signification. To cite an example, Pérez Pariente (2016) recalls a great character in the history of Alchemy: the Swiss physician, alchemist, and philosopher Philipus Aureolus Theophrastus Bombastus von Hohenheim, who became famous as Paracelsus (1493–1541). One of the stories associated with Paracelsus states that talismans were widely used in their therapies with patients, along with other remedies. These talismans were metallic objects in which:

A series of signs or words of a magical nature were recorded with which they were intended to attract the healing virtues that supposedly emanated from the planet associated with the metal from which the talisman is made and which in turn governs different parts of the human body. In addition, the talisman was made at certain times under the influence of specific astrological configurations established by rules that the physician had to know, in order to capture his power in the talismanic object. (Pérez Pariente 2016, p. 39, our translation)

Another example that can be cited is an excerpt from *Dialogue of Cleopatra and the philosophers*, commonly attributed to Cleopatra the Alchemist, who was a well-known alchemist who lived in the third century and who possessed the secret of the philosopher's stone. This artifact refers to a “magical” material that would be capable to make the transmutation, that is, transforming ordinary metals in gold and also would have extraordinary

medicinal properties (Nummedal 2016; Pérez Pariente 2016). In the Dialogue from which is highlighted the following excerpt, Cleopatra discusses, through analogies and encrypted language, some principles of the alchemical tradition, more specifically the purification of matter through fusion (melting) by fire:

when you take plants, elements, and stones from their places, they appear to you to be mature. But they are not mature until the fire has tested them. When they are clothed in the glory from the fire and shining color thereof, then rather will appear their hidden glory, their sought-for beauty, being transformed to the divine state of fusion. For they are nourished in the fire and the embryo grows little by little nourished in its mother's womb, and when the appointed month approaches are not restrained from issuing forth. Such is the procedure of this worthy art. The waves and surges one after another in Hades wound them in the tomb where they lie. When the tomb is opened they issue from Hades as the babe from the womb. (Linden 2003, p. 45)

As noted in the quote above, the author uses analogies that deal with alchemical processes as something similar to a living organism. This type of analogy is commonplace in alchemical texts. The metaphor of human birth, for example, which is present throughout the excerpt, is commonly associated with the philosopher's stone. Another element that is present is the perception, common at the time, of an evolutionary line of metals. In this perspective, metals are all made of a common raw material in different evolutionary stages, so that the noblest metals, such as gold and silver, would remain unchanged even after being tested by fire and the most violent chemical reagents. The same would not happen with less noble, less evolved metals. There is, therefore, a vitalistic belief in an active mineral world, which had been repeated in many alchemical texts and symbols. In addition, it is possible to note the influence of Greek culture, in which *Hades* is mentioned, as a place where matter goes through maturation (by fire) until a rebirth arises. Hades, in this case, invokes the Greek belief of the existence of an inferior world, to where the souls of dead people go.

For yet another example, now at the interface with art, it follows an image of Hermes

Trismegistus, known as “the thrice-greatest,” as seen by the artist, writer, and doctor Daniel Stolz von Stolzenberg, in his work *Viridarium Chymicum*, published in 1624 (Fig. 1). According to Principe (2012), the historical representation of Hermes Trismegistus is the product of a complex overlap between Greek and Egyptian mythological and heroic figures, which may be a reflection of the possible emerging from the interaction between such elements.

Hermes was known as a kind of God of knowledge, the source of all wisdom, identified with Toth – the Egyptian God of science – and deeply associated with the history of Alchemy, which as a consequence is sometimes known as *Hermetic Art*. Principe (2013) points out that Hermes' productions did not have a direct relationship with Alchemy, which was instead continually hailed in Antiquity. Among the various tales that related and attached Hermes to the history of Alchemy, there is the story about the Emerald Tablet. According to tradition, the Emerald Tablet had been found in the hands of Hermes' corpse (Pérez Pariente 2016). This artifact contained a very brief text, which summarized the principles of Alchemy into a few lines, thus becoming one of the main symbols associated with the Great Art.

Analyzing the image of Hermes (Fig. 1), it is possible to observe Trismegistus holding a globe on the left, with the Sun and the Moon on the right, which are two common symbols in Alchemy – the Sun, associated with the father figure and with gold, and the Moon, or the maternal figure and the silver. Fire relates to fusion (in the sense of combining) between both metals, as well as the conjunction between the two figures. Still, it is possible to note that gold was seen as a natural evolution of silver and other metals considered inferior, a process which a human could accelerate through techniques involving *chrysopoeia*. Almost as a confirmation of this thesis (for the contemporaries), it has been registered that a natural metallic alloy of gold and silver (known as *electron*) was abundant in several deposits in Ancient Egypt. In other words, *electron* is a “material testimony” of the natural

Alchemy, Fig. 1 Hermes Trismegistus, by Daniel Stolz von Stolzenberg (*Viridarium Chymicum* 1624)

process of “maturation” from silver into gold (or a transmutation). All of this multiplies the possibilities of interpreting the analyzed image, reinforcing Roob’s (2003) remarks on this subject. Perhaps this polysemy is what opens up to different possibilities of engaging either with natural, spiritual, or subjective worlds, explaining why Alchemy remains alive today, as noted earlier.

Meaning Making in the Possible in Alchemy: The Role of Iconic and Symbolic Representations

To understand the process of signification in the construction and representation of alchemical knowledge, semiotics is used. Semiotics can be

understood as the general theory of signs (see section Semiotics) (Innis 2020), which deals with understanding how the process of signification occurs from the creation and manipulation of signs. To broaden this understanding, it is adopted the premise that the human being is a meaning maker (Valsiner 2013). Thus, human history is marked by the human’s ability to interact with the environment and to signify it, based on the creation and mediation of cultural tools called signs. A sign can be understood as any representation of an object that has a meaning to someone (Peirce 1894). Thus, in Alchemy, meanings about Nature were represented by certain types of signs that carried meanings about how phenomena were interpreted by alchemists. Such meanings also represented a worldview at the time, from the intersection of different types of knowledge

arising from mysticism, art, and science itself, as already pointed out.

In this perspective, it is important to highlight the concept of culture used in this entry. Here, culture is not considered as an entity or product of human action. This is because culture is constantly changing and influencing the development of human beings. As stated earlier, signs are cultural tools, created by human beings. In addition to being created, they act in mediation in the construction of new meanings. Thus, culture is considered as an active process of semi-otic mediation (Valsiner 2013), acting on both intra- and interpsychological levels, regarding the human being as an agent in the process of construction of meanings. In other words, alchemical knowledge, represented by iconography and symbolism, is not just a human construction or a cultural product; beyond that, it can be a semiotic system which mediates and regulates human actions, allowing construction of new meanings (at an intrapsychological level) and acting in an influential way in people's lives, even regulating behaviors based on mutual influence between subjects (at the interpsychological level).

Another important aspect is how the process of construction of meaning occurs, beyond the influence of signs in the roles of mediator or regulator. In this sense, it is considered that for every constructed meaning A, there is a non-A (Valsiner 1998), so that meanings coexist. Thus, the new (see section Novelty) (arises from the tension between meanings $A \leftrightarrow \text{non-A}$, which can be related to the idea of the possible emerging in the tension between two perspectives. The very idea of *chymistry*, presented earlier as a kind of hybrid between Alchemy and Chemistry, for example, represents a tension of meanings in the $A \leftrightarrow \text{non-A}$ model, though it paved the way to the subsequent distinction of these two fields of knowledge at the sociogenetic level in later centuries.

As another example of the dynamic $A \leftrightarrow \text{non-A}$, Silva and Macêdo (2018) bring up the philosophical idea proposed by Empedocles (c. 494 – c. 434 BC) of the existence of four elements as the root of all things: air, fire, water, and earth. According to the authors, the tension $A \leftrightarrow \text{non-A}$

is represented by the meaning constructed about the nature of the four elements (abstract $\leftrightarrow$ not-abstract). The idea presented by Empedocles that the elements are principles represent an abstract ontology in which air, fire, water, and earth are “inside” of the matter making part of their composition, even if it is not possible to observe it. This idea coexisted with the notion that these entities also existed in the concrete world, in a non-abstract ontology, as described by Aristotle in *The Metaphysics* (Aristotle 1933) about the qualities of the four elements. Therefore, the idea of the four elements (or their roots) lasted throughout the European Middle Ages, being the basis for building new alchemical knowledge, in the tension of the abstract $\leftrightarrow$ non-abstract, until the “early” chemists’ contestation of the ontology of such entities and the existence, in a much larger quantity, of the so-called chemical elements (Partington 1989). For example, from the seventeenth century, it was speeded the notion that the air was not an element (simple entity) but a mixture of many other kind of substance (oxygen, nitrogen, hydrogen, so on).

Similarly, some of these characteristics of the dynamics of the signification process in the previous examples: in the text attributed to Cleopatra the Alchemist and in the image of Hermes Trismegistus. In both, it is possible to identify some symbolic and iconic signs that represent meanings based on the interactions between mysticism, science, and art. Not only that, but also the tensions that can be explained by the model $A \leftrightarrow \text{non-A}$, which reveals the emergence of the possible in the development of new meanings and in the emergence of Chemistry.

In Cleopatra the Alchemist’s text, it is noted that the fusion is understood as a reaction with fire, to which materials removed from earth rely to reach their full maturity (it is implied that she was referring to gold, that is, to *chrysopoeia*). In this sense, the image of fire plays the role of mediator in understanding the alchemical process that is being described, extrapolating that of a flame. Apparently, Cleopatra is highlighting the purifying function of fire, which destroys but at the same time nourishes the embryo in the womb of Mother Earth, allowing the materials

to exhibit their glory and hidden nature. The idea of fire as a destroyer and, at the same time, a purifier points to the model of meaning $A \leftrightarrow \text{non-}A$, in which there is a tension between meanings: destroyer versus purifier. The image of *Hades* is summoned from mystical meanings – mythical or religious, as the passage through *Hades* (a metaphor for the purifying process of burning in fire) endorses the maturity of the materials. Once again, it is noted the tension of meanings $A \leftrightarrow \text{non-}A$, since the maturity attributed to the materials is compared to a rebirth, at the end of the highlighted section.

In the image of Hermes Trismegistus, it is possible to observe several iconic signs (Peirce 1894), such as the Sun, the Moon, the fire, as well as Hermes' representation itself. Once again, fire represents the process of fusion, which is agreed among alchemists. However, in the representation of Fig. 1, fire has an additional function, aside from the purification proposed by Cleopatra: allowing the union (or fusion) between the feminine (Moon) and the masculine (Sun). This function of fire can be related to the idea of fertility, since the fusion between the Moon (silver) and the Sun (gold) gives rise to a new "metal": the *electron* (Oppenheim 1966; Morioka and Silva 2012). The iconic image of Hermes guiding the possible production of *electron*, from the fusion between gold and silver, expresses the importance of the figure of the alchemist for the Great Art, with the aim of manipulating the natural world. Thus, alchemists' work went beyond mere technique to be somewhat sacred, once again representing a tension of opposite meanings: technical knowledge developed by the alchemist based an empirical notion to understand the nature, and sacred involved in the development of the Great Art (sacred/mystic $\leftrightarrow$ not sacred/scientific).

A point of convergence between the works analyzed (the text and the image) is that both deal with the fusion process. While Cleopatra highlights the role of fire in her text, Daniel Stolzenberg represents fire as it combines silver (Moon) and gold (Sun) in order to create the *electron*. All of this is related to the processes of signification around alchemical signs. However, it

is seeker to approach the possible on the threshold between Alchemy and Chemistry, so one may be wondering: where is chemistry in all of this? What remains of these processes and what changes? Currently, one can associate the studied alchemical processes with two transformations that, in a certain way, show similarities with the meanings attributed in Alchemy: a change in physical state (melting) (Eq. 1).

Taking as an example the simplified representation of fusion of lead (Eq. 1), which can be found in any chemistry textbook, it is possible to see the use of some symbolic signs, whose meanings have been defined in the scientific field of Chemistry: "Pb" indicates the element (or elementary substance), a way of representing the chemical elements that follows from Jacob Berzelius' (1779–1848) proposition in 1813. The letters "s" and "l" between parentheses represent, respectively, the solid and liquid states of lead, before and after the transformation occurred (the fusion process). In turn, using equations (like the one shown above) to express a chemical reaction was proposed by Antoine-Laurent de Lavoisier (1743–1794), but initially with the "equal" sign (=) between reagents and products. It was only in the late nineteenth and early twentieth centuries that arrows began to be used for indicating a chemical or physical transformation in equations (Alvarez 2012). In any case, after this long leap in history, it is possible to notice that the iconic and symbolic representations, of polysemic and allegorical language, used in the alchemical period, gave rise to a type of language that prioritizes conciseness and clarity of information, so that the set of possible interpretations from such representation is drastically reduced. However, it should be noted that, aside from representation, furnaces, melting pots, and other instruments characteristic of *chrysopoeia* are still familiar in the practice of chemists today. Therefore, it represents a metonymy of the tension between change and permanence, which it was explored throughout this entry.

Conclusions

Though it may seem unlikely, the idea of the possible (Glaveanu 2020) in Alchemy resides in the fact that Chemistry, now recognized as scientific knowledge, originated from active dialogue with Alchemy, whose oldest traditions (previous to those of *Chymistry*) seem to be precisely the antithesis of what came to be Chemistry – with regard to relations with mysticism and art.

As previously highlighted, Chemistry did not arise from a rupture with Alchemy, but instead as a movement in which a certain set of practices, which characterized Alchemy, gave way to what came to be Chemistry as it is known today. It was, therefore, a more gradual process, as Klein (2015) describes for the so-called “Chemical Revolution” years later, at the end of the eighteenth century. Thus, *Chymistry* was understood as a hybrid between Alchemy and Chemistry in the emergence of the possible between these two fields of knowledge, considering that Chemistry had been developed as a science between the sixteenth and seventeenth centuries. Accordingly, at this time, some tensions with philosophical ideas come up, such as classifying water, earth, air, and fire as elements, which is, not exclusively, but ultimately refuted in the book *The Sceptical Chymist* (Boyle 1800). At the same time, several theories whose roots went back to alchemical ideas also existed, such as the existence of a fluid that caused bodies to burn, called *phlogiston* (Klein 2015). Therefore, these tensions along the chemical revolution, in which the new is established from the contestation of the old, while also generates hybrids that coexist on the threshold between the old and the new. This is also true between Alchemy ↔ Chemistry, with the possible emerging from this tension and generating *Chymistry* as a hybrid of the existing tension between A ↔ non-A.

Based on the examples discussed in this entry, Alchemy developed from interactions between mysticism and art, both of which influenced the process of transitioning from Alchemy to Chemistry. The vitalism associated with metals, the destructive and purifying nature of fire and the

relationship between mythological figures and alchemical materials or processes demonstrate how nature was understood and manipulated, allowing the development of techniques and materials used today by Chemistry, such as fusion in metallurgy and formation of metal alloys.

if?,” Alternate Histories fulfill an important function in human thought about contingency, possibility, and change, acting as a stimulus, as an heuristic, or as a tool for the conscious manipulation of opinion and action. Defining Alternate History broadly as a fundamental feature of the way humans explore possibility, this entry discusses prominent examples from literature and film, politics, religion, scholarship, and sport. It explores conceptual and ethical boundaries, inviting the reader to consider the function of Alternate Histories within societies, and what their use tells us about the way humans think about past, present, and future.

Alternate History

David Hamon and Dirk Niefanger
Friedrich-Alexander University Erlangen-
Nürnberg, Erlangen, Germany

Abstract

Alternate Histories are stories told in a version different to the one dominant in collective memory and are a common feature of human culture, present and past. They serve as a tool for exploring the boundaries of the possible and indeed are sometimes used to expand these boundaries. While historical narratives which diverge conspicuously from recorded history are often found in literature and film, Alternate Histories are in fact a common feature of our everyday lives: We find them in private conversations about societal change; in the appraisal of historical events of public concern; and particularly in the realms of the political, the religious, or in sport. As the kinetic exploration of the question “What

Alternate History

The term Alternate History (“alternative history” in British English, or “uchronie”) describes all possible forms of narratives of the past which first are of public concern, and second, differ materially from historical narratives in common circulation. Both types of historical narrative, alternate and common, ostensibly claim reference to genuine occurrences, yet Alternate History contains divergences which may be signposted, or go unacknowledged. This definition through apposition to “historical narratives in common circulation” as opposed to “historical truth” assumes that such truth remains forever elusive: History exists only as a narrative, often expressed in textual or image form, and is invariably subject to rhetorical and esthetic distortion (White 1981, 2010). Even material sources must be interpreted and incorporated into a narrative.

The moment of origin of any Alternate History is almost always a concrete point of divergence, from whence this world or another is differently

perceived, interpreted, narrated, or created. Through their pivotal nature, these moments illuminate a latent property of every history told or lived, the existence of moments of contingency, determined by surrounding events and the more-or-less random paths of possibility which emanate from them. In highlighting the contingency innate in every story, Alternate Histories impress upon us that it might all have been different and been told differently. They show us that our lives may have differed.

According to our definition, the phenomenon of Alternate History surrounds us in everyday communication. We can observe examples in private conversations about societal change, in the appraisal of historical events of public concern, and particularly in the realms of the political, the religious, or in sport. To define Alternate History as more than just as a specific category of text (a genre or subgenre of science fiction) is to defy dominant lines of literary-theoretical thought. Yet in view of the predominance of the phenomenon in diverse areas of modern culture, it seems apposite to take a more open and yet nuanced approach. The telling of stories, of history, is one of the most elementary acts of human culture (Koschorke 2012), and we understand Alternate History simply as a story told in a version different to the one dominant in collective memory.

In presenting historical alternatives, these stories serve a purpose. They attempt to facilitate communication by bringing clarity in the expression of a position, by contributing to the persuasive power of an argument, or by highlighting the potential for correction of perceived social or other ills, etc. Just as much a common (but not necessary) feature of Alternate History as the conscious – and possibly carefully exhibited – signposting of divergence, is the latent, hesitant, or sharply critical reference to the dominant version. Indeed, through this reference manifests often an added rhetorical, polemical, argumentative, didactic, political, or ethical value, which may serve a purpose in the present, near, or distant future.

However, we cannot view every form of alternative reference to the past as Alternate History, as not every such reference can be called “history.”

Instead, the term refers only to those stories which can contribute to the interpretation of societal, political, and cultural change (including potential future change). Only this type of narrative is defined as history and differs thus from most private or family memories and stories.

Accordingly, Alternate Histories exist always in relation to the collective memory of a particular time (Halbwachs 1950; Ertl 2017), and to a culture of memory in a certain place, with its specific social practices (Burke 1989, 97–113). This means that Alternate Histories cannot be fully understood without specific reference to their social context. Put simply, if an audience does not know the dominant version of the story to which an Alternate History makes reference, the added value will be missed. A specific understanding of an Alternate History is therefore bound to a specific “cultural memory” (Assmann 2011a, b), and the characteristics of this cultural memory, its retrievability and its potential as a tool for (philosophical) discovery, are of great relevance. One could even propose that an ideal purpose for Alternate History is the comprehension and critical reflection of a particular cultural memory. Yet here, we must note that the societal process of remembrance may be destabilized by Alternate Histories which serve to relativize and call into question the validity of a particular dominant cultural memory. Particularly in the social and political worlds, Alternate Histories thus harbor a dangerous potential to affect social cohesion and societal function.

Alternate History and Politics

Although the term “alternative facts” was first introduced to political discourse in 2017 by Kellyanne Conway, press secretary of former US President Donald Trump, the phenomenon it describes has existed much longer, probably just as long as human political interaction itself. Political goings-on in particular are open to interpretation according to ideologies or worldviews, and there is much room for conscious manipulation. A certain selection, evaluation, creation, and weaponization of evidence gives rise to the building

blocks of a politically effective narrative, which can differ from established versions, particularly where falsified facts are present in the architecture. If skillfully inserted into public discourse, “alternative facts” can contribute to a change in the structures of power, the destruction of societal consensus, or the destabilization of a political system – especially in western-influenced democratic societies (Rosenblum and Muirhead 2019).

Prominent recent examples of such “gaslighting,” consciously weaponized in political discourse, can be found in Donald Trump’s revisionist relationship with clear historical fact. The former US President utilized Alternate Histories in order to present himself as successful, to conceal potential shortcomings of his government, or to nurture a particular political vision. It was to these ends that he claimed the presence of a larger number of spectators at his inauguration than were truly recorded; that he denied having tested positive for COVID-19 before his first presidential debate with Biden; and that he contested the validity of the results of the 2020 US presidential elections. One might assert that “Truth Social,” the social network he created after his time as President, exists also to spread and utilize politically the power of “alternative facts,” or Alternate Histories.

In Central Europe, one particularly impactful Alternate History was the *stab-in-the-back myth* (*Dolchstoßlegende*), a widespread conspiracy theory propagated by the upper echelons of the German Army after the end of the First World War. Originating in a misrepresentation of statements made by British General Frederick Maurice, this particular legend was popularized by Paul von Hindenburg (later German Reichspräsident) through his statements before an investigative committee of the Weimar National Assembly in 1919. It alleged that it was neither the lesser fighting power of the German military, nor the poor leadership of those in command which led to defeat in war. Instead, the loss was instigated by “unpatriotic” elements of domestic society such as social democrats, intellectuals, and Jews through their actions at home. The German Army thus remained technically undefeated in combat. This myth and its prominence contributed materially to the destabilization of the Weimar and Austrian

Republics, and to the strengthening of right-wing conservative, fascist, and national socialist movements throughout Central Europe.

Alternate History and Historical Scholarship

There is a clear distinction between the problematic weaponization of counterfeit histories on the politico-ideological battlefield, and the construction of a contrafactual history for heuristic purposes in scholarly discourse (Evans 2013). In this context, a constructed history is a thought experiment in historical scholarship, methodically akin to similar practices in (analytical) philosophy (brain-in-a-vat, etc.). In contrast to Alternative Histories in political discourse, those in historical scholarship keep their constructed and experimental nature visible. Such histories which conspicuously diverge from empirically attainable truth can highlight continuities, divergences, structural relations, key agents, exigencies, and assumptions of responsibility relative to dominant narratives. As a form of presentation, Alternate Histories may also enable a greater didactic effect, or simply be more fun, and their value in teaching is thus indisputable. This methodical historical speculation must be kept distinct from examples of *future history* – a fictitious history regarding future events – whose purpose tends more toward entertainment (e.g., Jack London: *The Unparalleled Invasion*, 1914).

The use of counterfactual history in the exploration of historical relationships is naturally contentious, yet it is widespread in value-based judgments and considerations. Here, the boundary between targeted conceptualization and fantastical speculation is blurred (Did the Hiroshima Bomb truly save the lives of thousands of American soldiers? Would millions of Jews have survived if Georg Elser’s 1938 attempted assassination of Hitler in the Bürgerbräukeller had been fruitful?, etc.).

The methodical use of Alternate Histories in scholarly discourse must be distinguished from the spread of ideologically motivated, obscured, and obscurant counterfeit or pseudohistories (David Irving’s Holocaust denial, etc.). These

histories often have a large following, with members uniting in a sect-like manner and speculating on large-scale conspiracies. Counterfeit histories may be spread without an overarching political objective, intending instead to attract attention, popularity, or garner economic advantage. For example, in order to highlight the barbarism of the Middle Ages and to contrast it with the more favorable contemporary civilization, the nineteenth century produced the phenomenon of the Iron Maiden. This brutal torture device was allegedly put to use in medieval torture chambers and yet was in reality entirely invented (it can now be seen in the San Diego Museum of Man or in the Kriminalmuseum in Rothenburg ob der Tauber, Bavaria).

The scholarly value of Alternate History has been formally recognized. In 1993, Douglass Cecil North and Robert William Fogel received a Nobel prize for a process of counterfactual analysis in economic history, yet other theories have achieved greater popular renown. Herbert Illigs' *The Phantom Time Hypothesis* is one such example. A publicist by trade (and untrained as a historian), Illigs asserts that the entirety of mainstream medieval historiography is in fact a long-accepted Alternate History, arguing that a period of 300 years between 614 and 911 was invented by contemporary rulers for reasons of power. After scrutiny, these theses seem to be guided less by methodical interest, and more by a desire for media attention and economic gain.

Alternate History in Religious and Ecclesiastical Thought

The importance of the dissociation and occasional appropriation of Alternate Histories in religious discourse is aptly demonstrated by the process of canon formation in almost all religions (Tanach in Judaism; Holy Scripture in Christianity, with differences in Roman-Catholic, orthodox, and evangelical churches; Qur'an; Daozang; etc.). Of course, historical truths in religious thought are based upon different types of qualification as the truths of historical discourse. However, even – or perhaps especially – here, one can observe various portrayals of events in competition. In the process

of canonization, historical narratives are accepted as truth and put to use, or they are rejected and discarded (Biblical Apocrypha; apocryphal acts of the apostles; apocryphal gospels; letters; etc.). The reason for entry into canon and survival as an alternative tradition varies. It is due to alleged divine revelation; due to resolutions of religious bodies; or simply due to an inexorable creeping spread of the narrative. With this sort of genesis, one naturally finds certain regionally, socially, or ethnically delineated differences in validity of alternative narratives. Indeed, it is not seldom that Alternate Histories in religion come to form the basis of separatist religious practices and sect-like church formation. Here, one finds not only alternative religious traditions forming the basis of belief (Pentecostalism; New Apostolic Church; etc.), but also church-related historical events which are differently interpreted or narrated (Rastafari; Falun Gong; Jehova's Witnesses; Adventism; etc.).

One well-known expansion of canon (therefore a religious Alternate History) is Joseph Smith's *The Book of Mormon* (prophetic revelation or 1830), which became the religious basis of the Mormons, or *The Church of Jesus Christ of Latter-day Saints*. In it, the narrator tells of religious experiences and personal divine revelation. The spread of this narrative had a significant influence on concrete political events in Illinois (e.g., the murder of the presidential candidate Joseph Smith) and on the development of a fairly widespread religious community.

Alternate History and Sport

Alternate histories are found even in those places where we are used to seeing clear victors and losers, concrete rules, and – with the use of modern technology – fully transparent processes. In sport, three types of impulse tend to set an Alternate History in motion: suspected cheating; alleged action on the part of those not authorized to be involved; and controversial decisions by referees and other officials. Accordingly, the story of England's victory against Germany in the 1966 football World Cup is told in each country in an entirely different manner.

Not only the competition, but also the biography of the sportsperson themselves is relevant for the construction of divergent narratives in historical sporting achievements. This is shown in the different judgments passed upon sportspeople such as Lance Armstrong in cycling (doping; involvement in health politics; and cancer-illness) and Muhammad Ali in boxing (conscientious objection to military service; political statements; and Parkinson's disease). In both cases, autobiographical texts and interviews contributed to the biased stylization of these sportspeople in alternative narratives.

In the field of motivational coaching in sport, Alternate Histories are well established as a potent means for improving performance. In this context, some examples appear as mere grandiloquence, others as conscious misrepresentation, all for the aim of wrestling the seemingly impossible toward the frontiers of possibility. Surprise victories of underdogs often result from such motivational tricks (Greece versus Portugal, 2004; Muhammad Ali versus Sonny Liston, 1964).

Alternate History as a Cultural Phenomenon

In the field of culture, Alternate History can be understood as a type of fictional diegesis defined primarily by content. The phenomenon occurs across different genres and media (literature, films, games, etc.) and can therefore be described *à la* Genette as “a universe rather than a train of events (a story).” “The diégèse is therefore not the story but the universe in which the story takes place” (Genette 1988, 17).

The diegeses of Alternate Histories in culture originate from particular moments of our real history, constructing from these entirely new worlds. They can reach far into the future, or at least force us to think about our future differently than we otherwise would. For as with all historical fiction – an umbrella term for all forms of fictional speech and script which deal with history – Alternate History is based superficially on the past but in fact provokes thoughts of change in the present and future. Every sketch of an Alternate History indicates just as much the deficiencies of reality as

it does possibilities for improvement; indeed these possibilities are “played out” and “tested” in various scenarios. In this sense, diegeses of Alternate History construct multifarious spaces of possibility in past, present, and future. They begin with a point of divergence, from whence history marches forward along a different path to the one we recognize. The impulse for this comes from the conspicuous modification of well-known and relevant historical events (Hitler's suicide; Kennedy's murder; American Civil War; etc.).

Alongside simple linear narration of Alternate History (Philipp K. Dick: *The Man in the High Castle*, 1962; Robert Harris: *Fatherland*, 1992), one also finds related constructions such as the experience of an historical world running parallel to our own (Stephen Fry: *Making History*, 1996; Eric Flint u.a. *1632/Ring of Fire*, 2000 ff.). From the perspective of a modern-day audience, one could also interpret certain examples from the realm of science fiction as a specific type of Alternate History, where the real future has overtaken a constructed one (Arthur C. Clark/St Stanley Kubrick: *2001. A Space Odyssey*, 1968, George Orwell: *Nineteen Eighty-Four*, 1949). A notable characteristic of Alternate Histories in culture is that they often contain futuristic inventions – typical elements of science fiction. In Thomas Ziegler's *Stimmen der Nacht/Voices of the Night* (1984/1993), we find little espionage-robots just after 1945; in Kerry Conran's film *Sky Captain and the World of Tomorrow* (2004), there are powerful drones active in 1939; and in Timo Vuorensola's *Iron Sky* (2012), the Nazis land on the moon in 1945. As a sort of thought game, Alternate Histories are not seldom utilized for satirical effect, using forms such as parody and travesty, alongside more serious variants such as the contrafactum and the Dionysian imitation.

One famous example of a global Alternate History is the TV-series *The Man in the High Castle*, (Amazon 2015/2019), which tells the story of a United States defeated by the German national-socialists and the Japanese fascists. The point of divergence is the 1947 victory of the Axis powers in the Second World War, who have divided the world between them. Just a few isolated, impoverished, more-or-less independent zones are still in existence, including in the

USA. A Cold War hangs between the Japanese and German empires, with replaying moments of the real postwar history with alternative power-relations and ideologies. As the alternative diegesis, the series points to a parallel world documented in films. These films fall into the hands of the political resistance and depict a world not dissimilar to our own: The use of an atomic bomb is shown, and the Allies have won the war.

To a far greater extent than the original template, Norman Spinrad's novel *The Iron Dream* (1972), the series raises the question as to whether esthetic motives in production have been allowed to dominate over ethical and didactic ones. One might ask whether Alternate History has provided a vehicle for a concealed indulgence of fascist esthetic (Haupts 2016, 148). This could be found in some of the extravagant marketing ventures (even partially forbidden) which played on visual taboos, and in the ostentatious architectural design of the fascist worlds depicted. Although both aspects doubtless promote the success of the series, the ethical question must be asked as to whether the ambitious marketing and design elements – often superfluous for the story – can be justified in the context of real history (see below passage on philosophical esthetics).

Examples of Alternate Histories can be found in diverse areas of present culture, brought to life through various media: In novel form (Ungulani Ba Ka Khosa: *Ualalapi*, 1987; Christoph Ransmayr: *Morbus Kitahara*, 1995; Philipp Roth: *The Plot Against America*, 2004; and Martin Walker: *Germany 2064*, 2015, inspired by ATKearney's FutureProof strategy), in film (*Philadelphia Experiment II*, 1993; *Watchmen*, 2009, David Wnendt: *Er ist wieder da*, 2015, inspired by the book from Timur Vermes), in TV-series (*Star Trek: The City On The Edge Of Forever*, 1967; *The Man in the High Castle*, 2015 ff.), in docufiction (*Der dritte Weltkrieg*, 1998; C. S.A., 2004), in video games (*Civilisation*, 1991 ff.; *Wolfenstein 3D*, 1992 ff.; *Command & Conquer: Red Alert*, 1996), and in role-playing games (*GURPS*, 1986 ff.; *Crimson Skies*, 1998 ff., und *living history* projects). Alternate History is discussed in online platforms and electronic

magazines (Forum *Alternate History Discussion*, 2010 ff., *Changing The Times*) and has been the subject of scholarly research since the 1950s, although not intensely until the 1980s (Prucher 2007, 4–5).

In the context of philosophical esthetics, Alternate History invokes the traditional creative freedom of historical fiction (e.g., Shakespeare, Racine, Lessing, or Schiller). The basic argument always runs along the lines of Aristotle (Poetics, 9): Real history may be changed in a fictional context if it serves the intended esthetic, didactic, or political function. However, main characters (Hitler, Ivan the Terrible, etc.) and most important events (Holocaust, American independence, etc.) may not be gratuitously changed. This poetic license is interpreted by Alternate Histories in the widest sense, resulting in brave excursions into regions often regarded by traditional historical fiction as taboo. At the same time, however, the diegeses of Alternate History presuppose and require knowledge of true historical actors and the common narrative of history. Only then can they impart their intended effect, especially regarding future political and social development. Where this effect is present, Alternate Histories are powerful, and not just as stories. Indeed, they say more about the way we think about the future and the familiar models we use to this effect, than they do about the past.

Summary

Alternate Histories are stories told in a version different to the one dominant in collective memory and are a common feature of human culture, present and past. They serve as a tool for exploring the boundaries of the possible and indeed are sometimes used to expand these boundaries. While historical narratives which diverge conspicuously from recorded history are often found in literature and film, Alternate Histories are in fact a common feature of our everyday lives: We find them in private conversations about societal change; in the appraisal of historical events of public concern; and particularly in the realms of the political, the religious, or in sport. As the kinetic exploration of the question “What if?”,

Alternate Histories fulfil an important function in human thought about contingency, possibility, and change, acting as a stimulus, as a heuristic, or as a tool for the conscious manipulation of opinion and action.

American Pragmatism

Steven Lybrand
Palo Alto, CA, USA

Abstract

By the end of the nineteenth century, a small group of North American intellectuals known as the Pragmatists had laid the foundation for what became the dominant movement within American philosophy for the next half century. Charles Sanders Peirce, William James, and John Dewey were part of the first generation of thinkers to confront the implications of Darwin's theory of evolution by natural selection. While different in many ways, all three agreed that previously held beliefs regarding the “possible,” the “a priori,” and the “necessary” in thought and/or nature had been upended by Darwin's findings. With species and ontological categories no longer established by design, the category of “the

possible” became alive in a way it had not been previously. Deterministic philosophies of both idealist and materialistic lineage were replaced by more experimental approaches to the evaluation of beliefs and practices. The original Pragmatists fashioned themselves as revolutionary thinkers, with intellects and personalities custom-forged so as to be able to offer unique perspectives regarding the possibilities of contemporary life. These thinkers/practitioners might be seen as potential exemplars for those who wish to work firsthand with complex experiences and cultural phenomena. This entry will review the major ideas of the American Pragmatist lineage over time and provide a rough sketch of the *possibilities* for a uniquely inspired form of ***Pragmatist Intellectual Craftpersonship***. This entry concludes with a brief review of the contributions of the Neo-Pragmatist Richard Rorty and some of his critics – including the so-called New Pragmatists – to bring the story of Pragmatism up to date.

The Possibilities of Pragmatism: The American Tradition(s)

In 2009, the American journalist A.J. Jacobs published a summary report of a number of informal experiments he had conducted over the preceding 15 years. In *My Life as an Experiment: One Man's Humble Quest to Improve Himself*, Jacobs recounts his explorations within the most popular genre of the American book publishing industry: the self-help book (Jacobs 2009). In the bookstores that survived the online market incursion of the early twenty-first century, shelves and even whole aisles are devoted to the almost endless variants of the self-improvement manual (by the second decade of the present century, subscription websites and podcasts have become the favored conduit for the self-help “content providers”/entrepreneurs). Jacobs undertook a series of tests which probed some of the ideas, beliefs, proposals, practices, and worldviews prevalent in the genre using himself as the subject (earlier drafts of the work were entitled *The Guinea Pig Diaries*). Reminiscent of William James’s participant observation studies of transformative religious beliefs and practices more than a century ago (James 1902), Jacobs says he undertook the experiments because he was fascinated by all that was available to people who were “. . . committed to the possibility of change” (Jacobs 2009). If the American experience with self-improvement practices is the sampled universe (and Aristotle’s canonical distinction between “Possible” and “Impossible” events/knowledge is still seen as viable), the “Possible” and “Potential”/“Contingent” stocks continue to trade as high as they always have in America, while the darker, more skeptical “Impossible” and “Necessary” shares continue to trend downward (except perhaps in the sociology, environmental studies, and literary criticism departments) (Aristotle 1952).

The journalist Jacobs follows in a long line of American intellectual and cultural explorers – led by those historically identified as “Pragmatists” (in the philosophical sense) – who believe that discerning differences between various belief systems and philosophical perspectives cannot be decided in the abstract but must be investigated

personally by the researcher him or herself. The early Pragmatists, Charles Sanders Peirce (1839–1914), William James (1842–1910), and John Dewey (1859–1952), argued that distinguishing between the possible and the impossible in logic, philosophy, and life cannot be established by dicta, determined by tinkering with the ancient *a priori* or modal categories of possibility/necessity/actuality/contingency/potentiality or even by the long-established scholarly practice of writing books based on other books (Peirce referred to those who chose the self-referential, scholarly approach as “philosophers bred in theological seminaries”) (Peirce 1897). Positioning themselves as part of the first generation of thinkers who understood the radical implications of Darwin’s theory of evolution for philosophical and social analysis, the Pragmatists dismissed much of nineteenth-century thought as nothing more than the idle speculations of those taken with absolutist, otherworldly specters. In contrast, the Pragmatists advocated a muscular firsthand examination of the beliefs and practices of a new generation of recently urbanized Americans who James saw as confronting “live possibilities”; that is, “modern” individuals coming to grips with, in the words of Ian Hacking (1936 -) “. . . real life, real knowledge, real expertise” (James 1907; Hacking 2007).

The Pragmatists’ methodological principles held that for one to understand the live possibilities of both self and others, each individual must, in an unadorned, personal way, “take a look” around the actual world and see which ideas and practices survive the tests of that world. For Peirce and James, a proper test was not an armchair academic exercise but a careful and systematic sorting of the real-world *consequences* of ideas, concepts, and behaviors. As part of this rigorous vetting process, one would compare one’s own conclusions with those of others – both predecessors and contemporaries – who have worked the same experiential territory and who have conducted their own customized tests of what was deemed to be possible (at least potentially). While such a Pragmatist DIY (do-it-yourself) exhortation may strike some as naive, especially in a post-Kuhnian, postmodern world, this “take a

look” approach of a journalist such as Jacobs is, in miniature, the upshot of the Pragmatist message since Peirce, James, and Dewey first announced it in the late nineteenth century. Although made more complicated by the various forms of post-modern skepticism regarding so-called “raw experience” or “empirical” evidence, the “sort it out for yourself” message continues to resonate both in parts of the academy and in the larger public which confronts the plentitude of cultural phenomena daily.

Although this entry will not explore the topic, there is another meaning of “American pragmatism” extant. This nonphilosophical sense of “being pragmatic” concerns a certain no-nonsense, bottom-line, “show-me-the-money” sentiments and behaviors popularly associated with a stereotypic conception of American society and culture. Exploring this more brawny cultural imagery of everyday matters would require more extended treatment. Thus, this entry focuses on North American philosophical Pragmatism.

If there is one attribute the American Pragmatists covered in this entry share (even when differing on others), it is an abiding commitment to the idea that the meaning, value, and sometimes the truth of significant beliefs and values can best be determined by looking, not primarily backward to the past, but ahead to the future, in search of the possible consequences of holding and acting upon particular views or beliefs (Thayer 1968). Related to this “focus-on-the-consequences” commitment, the Pragmatists under consideration here promoted an open-ended search for potentially useful knowledge, understanding that, at best, this knowledge would be of a provisional nature only. They all opposed a notion of inquiry that promised to reach an illusory, final certitude or Truth with a capital “T” (the abhorrent “Eternal” or “Absolute” in nineteenth-century thought). James’s formulation of this provisional conception of knowledge in a post-Darwinian world focused on the brain as an exploratory, hypothesis-creating organ that evolved to deal with an ever-changing environment. In this context, he said, “The brain is an instrument of possibilities, but of no certainties” (James 1890).

Utilizing a similar exploratory mindset, Jacobs describes his experiments and reviews the consequences that followed from them. He also discusses what possibilities (in the form of new experiences, expanded behavioral options, even awareness of alternative/possible worlds, i.e., worldviews) his experiments opened up for him personally. A small sampling of his reports is offered here as a contemporary entrée into the American Pragmatist worldview in which the demand that we test out for ourselves the various and competing beliefs and practices circulating in society can be considered as the most serious intellectual (craft)work a curious and engaged person can hope to do. The contributions of a small number of thinkers within the Pragmatist tradition will then be reviewed, starting with the original three of Peirce, James, and Dewey. Following a core Pragmatist principle, the remainder of the entry will trace out the *consequences* of some of their beliefs in the form of their influence on a select number of thinkers who followed their lead throughout the early and mid-twentieth century. The entry also looks at the contributions of the Neo-Pragmatist Richard Rorty (1931–2007) and some of his recent critics – the so-called New Pragmatists – to bring the story of Pragmatism up to date.

Working with Experience Firsthand

The centerpiece of this entry will be to offer up a rough sketch of the *possibilities* for a uniquely inspired form of ***Pragmatist Intellectual Craftpersonship***. The Pragmatists discussed here were all exceptionally creative and methodologically sophisticated thinkers who saw themselves as confronting the modern world in very personal, particularized ways, with themselves as the self-created instruments to be used in analysis. They fashioned themselves as revolutionary thinkers, with intellects and personalities custom-forged so as to be able to offer unique perspectives regarding the study of the possibilities of modern life. All those discussed here can be held to be possible exemplars for those wishing to work with and handle complex experiences and

phenomena firsthand, in vital and perceptive ways. The historian of ideas Jacques Barzun (1907–2012) asserts that William James preferred to analyze experiences personally and full on; in James’s own words, James said he preferred to “handle them bare” (Barzun 1983). As an example of this type of approach, James conducted a study of religion not by relying solely on theological treatises or other abstract/formal systems of metaphysical thought but by attending to the actual (and recorded/recounted) experiences of people who claimed to have been in touch with “the unseen” or other alternative-world phenomena (James 1902). For James, this engagement required he personally participate in religious rituals, including séances and other intense intersubjective happenings to observe/experience the phenomena himself. James thus advocates that one start one’s study of any subject afresh, taking a look for oneself even if the weight of scholarly tradition and societal custom declare the matters as fully settled by previous or current “authorities.” This “bare hands” approach to working with cultural material might be said to best characterize the craft-like, DIY interpretive practices of the Pragmatists. Their form of first-person treatment is the forerunner to Jacobs’s informal studies, the latter reviewed briefly here to give a flavor of how a contemporary American journalist exemplifies the craftwork tradition made famous by Peirce, James, Dewey, and others (in a European context, this craft form of cultural analysis or bricolage can be seen in its full flowering in the work of Roland Barthes).

Intrigued by a research study he read of the deeply corrosive effects of a world overrun by too many interpersonal demands and technology-driven cognitive distractions (an accentuation perhaps of William James’s reference to the “great blooming, buzzing confusion” [James 1892–1958]), Jacobs spent a month attempting to limit his waking hours to “unitasking” (the proposed therapeutic alternative to multitasking). As he attempted to focus on completing one task at a time, he quickly realized that his frenzied *habit-driven* everyday life patterns (such cognitively dulling habits being another realm explored in depth by James) were accompanied by so much

mental noise – accentuated by his obsessive real-time monitoring of his personal technology devices – that he was surprised he had previously been able to get any work done at all. As part of the experiment, Jacobs started using a manual typewriter while working (a strategy implemented to avoid the temptations of the Internet). In an informal phenomenological sense, Jacobs reported noticing interesting things that occurred in the sensations he perceived when typing on a manual typewriter and in his perceptions when seeing his words appear instantaneously on the *material page* (bypassing the computer-to-printer-to-page loop).

Curious about how this immediacy was affecting his thought process and written expression, he recalled that Nietzsche's writing style changed when his memorialization practice shifted from writing longhand to composing on a typewriter. In an insight that would have resonated with Peirce, James, and Dewey (all of whom were interested in how the direct, personal nature of self-discovery affected one's everyday behavior and practices), Jacobs seemed to grasp in an intimate way that the shift in Nietzsche's writing style – from a "more flowing and discursive (form) to more telegram-like, bulleted, and epigrammatic" style of his later work – was perhaps due to a shift in the material technology he used (Jacobs 2009).

After a month of this unitasking experiment, Jacobs discovered, among other insights gained, that he was able to, in his own words, get control of his "brain's steering wheel" (as to the "consequences" of this test, he reports he was able to focus his mind enough to drive a car for the first time in years, an unexpected expansion of some real possibilities in his life). Peirce, in a practice he shared with his fellow Pragmatist James, was himself interested in the expansion of possibilities in one's intellectual life through, paradoxically enough, the channeling and disciplining effects of habits on one's thoughts that come from paying close attention to the effects of small changes in one's personal thinking and the consequent conduct (paradoxical in the sense of the nonobvious effect that a *narrowing* of focus can lead to an *expansion* of imaginative possibilities) (Peirce 1878; Hudson 1966).

In a craft practice characteristic of the work of some later Pragmatists, Peirce and James both developed a lifelong habit of recoding in make-shift laboratory notebooks their everyday experiences, including the laying down of trail markers so that they could return to these experiences and problems later (well into his declining years, Peirce carried a small notebook on his person for the immediate capture of everyday observations and reflections – his "experiments" – even if his entries shrunk to just 25 entries per day by the end of his life!) (Feibleman 1946). In an article discussing the implications of a pragmatically inspired scientific attitude for the enlightened conduct of the proverbial everyday person, Peirce says, "If a man burns to learn and sets himself to comparing his ideas with experimental results in order that he may correct those ideas, every scientific man will recognize him as a brother, no matter how small his knowledge may be" (Peirce 1896). It is just this connection between the craft handling of everyday experience and the possibilities of knowledge and conduct that connects in a direct line the early Pragmatists to the later American scholarship in behavioral economics, judgment, and decision making and the shelves of practical books on making better decisions in everyday life (Duke 2020; Kahneman 2011).

In another experiment, Jacobs practiced something referred to as "Radical Honesty," in which he pledged to tell no lies – no matter how trivial or pressing the demand for "white-lie" social decorum. Reminiscent of Harold Garfinkel's (1917–2011) ethnomethodological "breaching experiments," Jacobs found it momentarily liberating to operate without the stultifying overlay of society's mores while talking with others (Garfinkel 1967). Jacobs also discovered that speaking disingenuously to others was built into the fabric of life for, apparently, some very good reasons (Habermas's ideal of distortion-free communication theory notwithstanding) (Habermas 1984, 1987). Words can be weapons that hurt others and by the end of this experiment with straight talk, Jacobs reported he had just lived through what was probably the worst month of his life. One might note in this context that William James was legendary for his forthrightness

and honesty in dealing with others. He was also known as having impeccable interpersonal manners in social situations. Jacobs's month of Radical Honesty may have unfolded differently had he also consulted/tested James's (strategic) accommodations to bourgeois life and tested those practices as well. Pragmatists of every stripe will see immediately that what Jacobs reports here is an example of the Pragmatists' (especially Peirce's) experimental or "laboratory" approach of putting real-life ideas and plans to the empirical test. This practice involves the engaged testing and sorting out of the consequences of one's thoughts and actions, and, through this process, coming to learn the true value or worth (and cost) of adhering to certain of society's customs or ideals.

In other experiments, to test the theory that IQ was hardwired, Jacobs read the entire *Encyclopaedia Britannica* from A–Z (the consequence of which was an unleashing in him of an unbridled curiosity for learning new things about the world he had not previously been aware of) and later lived for a year adhering to the rules of the Bible, the Ten Commandments, and beyond (he said it "... changed me in ways large and small. Perhaps most notably, it's given me a sense of gratitude [to others and for life].") In another experiment, Jacobs agreed to pose nude for an article written by a female actor who was exploring the objectification of women in the media industry. After sitting around a room for extended periods of time without clothing before a crowd of fully clothed photographers and young tech assistants, Jacobs says he was forever incapable of looking at popular media photographs of naked people without recalling the loss of control over self and the objectification required in the production of such images. The much-discussed capacity for, identification with, and empathy for, the suffering of the Other, as well as the complicated phenomenological act of perceiving our own bodies, is transformed when one's own self is offered up, not as an opportunity for theoretical speculation, but as an experiment or test of the "live possibilities" it may present for understanding self, the Other, and interpersonal behavior (James 1907; Rorty 1991).

Although Jacobs does not cite the American Pragmatists as inspiration for his self-fashioned experiments, he does claim to be practicing a form of "participatory journalism," a close relative to the "participant observation" social science research program that hails from the hotbed of American Pragmatism throughout much of the twentieth century: The University of Chicago (Bulmer 1984). This type of journalism/research taps into a central Pragmatist vein that fuels the imagination of those cultural explorers who are not put off by the puritanical hall monitors of positivism and can thereby expand – at least potentially – the storehouse of possible knowledge and action available to the human species by leveraging the unique experiences of every distinct individual. W.E.B. Du Bois (1868–1963), discussed below, was probably the first fruit of the early Pragmatist movement and his *The Soul of Black Folk* (1903) remains a classic of American social science channeled through the popular medium of journalism (a number of the essays in his 1903 classic were originally published in *Atlantic Monthly*).

In the next section, an orientation/practice referred to as Pragmatist Intellectual Craftpersonship is offered as the conceptual/practical space that arguably represents a powerful opportunity for expanding the possibilities for widespread knowledge generation and critical, democratic participatory action, the desiderata of many who consider themselves working in the Peirce, James, and Dewey Pragmatist tradition(s).

The Possibilities of a Pragmatist Intellectual Craftpersonship

One interesting connection between the cultural situation of the early Pragmatists and some features of the postmodern moment is the unabashedly personal nature of the content and expression of much of the knowledge in both eras (James's essays do not hide the fact that they are written by a full-blooded human being, no different in most ways than his own readers). With the expansion of technology, access to cultural content production by individuals has greatly expanded since the

early twentieth century (the expansion having been exponential since the beginning of the current century). People with Internet access and relatively modest computing and recording resources can not only consume huge quantities of cultural content, they can also contribute to it in an almost unlimited manner. And they often do so in the guise of what might be seen as the Jamesian pose of an individual simply sharing with others his or her unique perceptions and individualized experiences. The current cultural moment is indeed an opportunity for generating an unlimited number of the William James type of creative, romantic individual who could offer up their own personal and cultural prescriptions for examination/sorting out by the broader public. It is hard to imagine a more propitious opportunity for the generation of possible solutions to personal and societal problems that a vast interconnected network of individuals motivated to contribute – at least potentially – to the common good.

It should also be said in this context that it is not hard to imagine (as it is in the reported news daily) the potential for far darker possibilities given the capacity of the Internet to unite disparate individuals and groups into cabalistic and violent, sectarian movements. Many of the programs of these dystopian sects are far different in intent and design than the open, democratic, and tolerant forms of Pragmatist-styled problem-solving agendas highlighted here. Where one comes down on the potentiality issue relating to the liberatory or repressive possibilities/consequences of the explosion in information technology (and its control) is likely to be related to one's own general beliefs or (Manichean) world-views regarding the possibilities for democratic control of collective life in its current and/or future forms. At least as far as Peirce was concerned, while the future cannot be predicted with any certainty, he felt that it was the community of scientists, not the narrow-minded dogmatists, who were most likely to get things right and keep humanity on course for the unification of the species (Peirce 1893b). James similarly had an optimistic view of the future of humanity (even if he was periodically beset by incapacitating depression personally).

Given that our current cultural moment is awash with information of staggering proportion and hard-to-assess possibilities, it might be argued that individuals would benefit from a form of craftspersonship that guides them as they struggle to balance the desire for creating unique and useful knowledge (i.e., proposing innovative behavioral solutions to personal and societal problems) with the need to leverage the wisdom and the discipline of the past and current masters and critics who have worked the same territory they are surveying. It is the thinkers who have left their hard-earned laboratory notebooks filled with reports of paths taken and not taken that may best benefit those who wish to make original – but also efficacious – contributions. The courage to invent and share characteristic of much personal (or Internet DIY) content can only meet the Pragmatist test of success if the producers know how to listen to the voices of others, both supporters and critics, both predecessors and contemporaries, as it is in these voices that we can find methods of thought and action that others have found to be useful. Learning to consult/listen to these other voices without losing confidence in one's own unique perspective is the craft part of this practice. In short, what is needed is a viable model of craftspersonship for the new era. The twentieth-century Pragmatists (from Peirce and James through Du Bois and Dewey to Rorty and the Feminist-Pragmatists) have proposed various models for this and offer themselves as exemplars. The full menu of their unique forms of cultural analysis has not yet been fully vetted for possible forms of craftspersonship by our contemporaries (see Richard Sennett's *The Craftsman* [2008] for a development of this model and also Crawford 2009).

The need for such a rigorous and critical vetting of philosophic and cultural content was appreciated by the early American Pragmatists, who extended this form of inquiry to their own ideas. Peirce, James, Dewey, Josiah Royce (1855–1916), and the other early proponents of the Pragmatist message of testing out ideas and plans were themselves not satisfied to generate narcissistically self-referential knowledge content (notwithstanding their critics, who claimed

otherwise, e.g., Bertrand Russell 1945), even as they were committed to expressing themselves in an open, creative, and accessible way. Each of the Pragmatists mentioned here not only attempted to write in a clear manner accessible to the educated public of their day (granted, a demographically small sector of the American population), they also lectured widely to public audiences. As Peirce suggested above, their ideas about the utility of the Pragmatist craft were not part of a self-referential game played just by office-tethered scholars.

Peirce's immanently readable (even today) 1877 and 1878 statements introducing Pragmatism were published in *Popular Science Monthly* (perhaps a misleading image as that publication at the time was the hardly "popular" in any meaningful sense and was more philosophical than scientific) (Peirce 1877, 1878). The craft-like nature of his and the other Pragmatists' work seemed to exemplify the principle that while it was important for individuals to discover and create unique and even idiosyncratic ideas and plans, it was just as important to communicate these ideas in as accessible way as possible so they could be fully tested by others. One of the founding documents of Pragmatism referenced above was entitled by Peirce *How to Make Our Ideas Clear* (Peirce 1878). It is a model both of expression and of inspiration for those exploring future personal and societal possibilities. Peirce directed his comments in that essay to those people interested in the working with "... those vital and procreative ideas which multiply into a thousand forms and diffuse themselves everywhere, advancing civilization and making the dignity of man..." (Peirce 1878). Herein one can see the Pragmatist desire for direct communication with one's fellow citizens and a commitment to knowledge generation that suggests future possibilities for present and future human understanding.

Many of James's works (not all, certainly) are almost completely accessible even today to people whose education ended at high school. And he speaks in a self-deprecating tone that invites readers to disagree with, and even laugh at him, a Harvard professor of philosophy grown too big for his britches "... had they had a peep at my

strange indoor academic ways of life at Cambridge" (James 1892/1958). Dewey's desire to and capacity for communicating with children, teachers, and the broader public regarding his ideas about human possibilities was well known in his day but is worthy of another look by a current generation of social thinkers (that is if one does not take on faith Richard Rorty's recommendation of Dewey as our unparalleled "cultural hero." A two-volume collection of Dewey's work: *The Essential Dewey* published by Indiana University Press in 1998 is widely available and eye-opening to those who dismiss the Pragmatist message as superficial, Pollyannaish, and outdated) (Dewey 1998a, b).

Beyond a Promethean encouragement for the discovery/generation, and empirical testing of new ideas and practices related to human potential/possibilities and a desire to communicate with others in an open, inviting democratic way (or at the very least, a capacity for expression that escapes the gravitational pull of a narcissistic self-absorption), what other elements of thought and practice were modeled by the Pragmatist Craftpersons under discussion?

I would argue that the centerpiece of the Pragmatist craft is an imaginative, existential sensibility or desire to, and capacity for, understanding self and others in an open and genuine way. The three discussed here certainly strove to achieve a deep understanding of themselves and others in a more than an abstract, distance-enhancing, academic way. Here I will only briefly discuss Peirce as an exemplar but even a cursory survey of the works of James, Dewey, Royce, George Herbert Mead (1863–1931), W.E.B. Du Bois (1868–1963), Jane Addams (1860–1935), and others underscores the importance these early Pragmatists attributed to the need for and capacity to understand the voices of self and others as a prerequisite for Pragmatist Craftpersonship.

As is well documented, James was a "Pluralist" long before the American academy belatedly discovered the need to hear voices other than those of the actuarially miniscule Western, affluent, White male minority (Perry 1935; Barzun 1983). His craft studies of religious beliefs and practices are Pragmatist exemplars of the willingness and

courage to take seriously the voices of others, including those whose beliefs and practices are decidedly frowned upon by the sophisticated elites. The need to seek out and attempt to understand others is arguably still the greatest challenge to democratic possibilities and this challenge is demonstrated almost daily. For example, had there been more social scientists willing to venture out into the provinces in the run-up to the 2016 American presidential election, there may have been far fewer people surprised at the outcome when an authoritarian candidate disapproved of by the educated coastal elites won the election. And had more Americans been interested in and made aware of the conditions of life in the central cities (or of African American life historically through the pioneering works of Du Bois and others), the brutal killing of George Floyd in 2020 in the Upper Midwest of the USA may not have been perceived as so incomprehensible within nonminority North America. It is important to note in this context that although there is not space here to discuss more comprehensively the ethnocentrism/racism of the early Pragmatists, it is the subject of recent scholarship, starting with Cornell West's *The American Evasion of Philosophy: A Genealogy of Pragmatism* (West 1989). West discusses how the early Pragmatists and their followers to this day did not and do not appreciate "... the strategic role black people have played in the development of the capitalist economy, political system, and cultural apparatuses in America" (West 1989). Obviously much more needs to be done to understand the failure of Pragmatists across the history of the movement to understand the impediments to the seemingly endless "possibilities" they foresee in the American ideal faced by the communities of color, women, LGBTQs, and other groups/communities facing structural and endemic inequality, discrimination, and exclusion (Kautzer and Mendieta 2009).

Even with his ethnocentric perceptual blinkers, Peirce, the detailed-driven laboratory scientist whose day job consisted of measuring minute effects of gravitational fields on the earth's rotation, was also a creative polymath nearly obsessed with understanding and promoting human communication (pace his work on logic and his

"invention" of semiotics) and whose final philosophical formulation (left unfinished) was chasing something called "cherishing love" or "agape" (Peirce 1893a). To Peirce, the greatest sin of a human being was individual economic selfishness and an unwillingness to accept others as equal parts of the larger human community (his blindness to his and others' racism in this regard is also part of his legacy). It is not an exaggeration to say that Peirce's entire philosophical system was the lifelong promotion of the idea that the entire human species is a collection of individuals trying to make actual what is now only theoretically possible: the unification of the human community. His theory of signs was an attempt to show that genuine communication between people was not only possible but (eventually) guaranteed by the fact that each human being (when he or she got properly oriented) was really just a single investigator in the larger community of investigators introduced by evolution to help advance the human species. But even here, his idealist formulations were offered up for a Pragmatist-inspired vetting by others. To Peirce, *Evolutionary Love* was a cosmological hypothesis he thought had been well demonstrated over the course of history but he said he would be, "... fully content to await the final decision" (Peirce 1893b). In terms of the need of the Pragmatist Craftsperson to become self-aware, Peirce himself recognized that he may have lost some of his scientific precision when he blames the above metaphysical talk of his own on the fact that he was brought up among the Concord Transcendentalists, and although "... not conscious of having contracted any of that virus ['the monstrous mysticism of the East']... [n]evertheless it is probable that some cultured bacilli, some benignant form of the disease was implanted in my soul, unawares, and now, after long incubation, it comes to the surface..." (Peirce 1892/1893).

In addition to including the genuine desire for – if unevenly realized – understanding the humanity of others as part of the Pragmatist Craftsperson's toolkit, we might add the character trait of humility (Peirce understood this as related to his concept of "Fallibilism"). And perhaps supplement this trait with another early Pragmatist

characteristic: self-deprecating humor, a possible indicator of the capacity to see oneself as a democratic equal to all others (Rorty, in a different context refers to this trait as the capacity for “liberal irony”) (Rorty 1989). That the early Pragmatists themselves failed to fully understand or test the “consequences” of their ideas of democratic possibilities within the context of racial or gender differences is an interesting case study worthy of a James-inspired analysis of our near-inevitable “blindness” when it comes to understanding (certain) others (James 1892/1958).

Although the above discussion of Pragmatist craftwork is only a preview of the possibilities, it will be supplemented as the story moves forward across the twentieth century.

The Pragmatist Intellectual Craftsperson at Work: The Cases of W.E.B. Du Bois and C. Wright Mills

One measure of the importance of a philosophical/intellectual movement such as Pragmatism is provided by the criteria its originators set out themselves: How do the ideas, beliefs, and practices test out in the real world? More pointedly, what are the consequences or influences on others of the ideas as set forth by the founders of Pragmatism? What possibilities for knowledge generation, craftpersonship, and action did the movement generate? Some have argued that after the initial flowering of Pragmatism between roughly 1890 and 1945, the movement receded into the historical background of philosophy in North America, replaced by the logical positivism/empiricism of the Vienna School and then by analytical philosophy. This narrative reconstruction then creates the conceptual space for a later “Revival” of the original movement’s ideas. This arguably happened with the American Pragmatists (Dickstein 1998; Menard 2001). An alternative approach is seen in some recent archeological work on Pragmatism’s trajectory over the twentieth century. This “submerged historical continuity” narrative suggests a far deeper influence of Pragmatism on American intellectual life than previously understood (West 1989; Seigfried 1996; Kautzer and

Mendieta 2009). An understanding of the depth and range of the Pragmatist influence on twentieth-century thought is still in its infancy. This entry will present just two for consideration (and admittedly excludes Pragmatism’s greatest flowering in the work of those hailing from the Chicago school of sociology, starting with George Herbert Mead and continuing to the present generation of ethnographers inspired by the Pragmatists). However, although limited in depth and range, the discussion of the two here is indicative of how important strands of twentieth-century social thought can be tied back in direct and surprising ways to the expansion of possibilities for democratic thought and action laid out in the original Pragmatist intellectual imagination.

W.E.B. Du Bois’s life and work across the twentieth century is a powerful exemplar of Pragmatist Craftpersonship and its possibilities in the hands of a brilliant practitioner. Du Bois was a fifth generation American of African descent (West 1989). After attending Fisk University, an historically black college, he transferred to Harvard to study philosophy under William James and others. Du Bois reports, “I became a devoted follower of James at the time he was developing his Pragmatist philosophy. . . . James guided me out of the sterilities of scholastic philosophy to realist pragmatism. . . .” (Du Bois 1968). Du Bois went on to become the first American researcher to conduct “formal” empirical research of African Americans, publishing over 16 studies and a groundbreaking community case study of the Black community in Philadelphia, all before 1914. For Du Bois, it was not enough to theorize about race relations, one had to live in the actual community studied in order to understand from the inside the lives of the people he consulted/studied. Du Bois fashioned his own craft as he went along, changing his approach and his style of research as his thought and practice evolved. He published five novels and wrote on Black musical forms, arguing that the only way one can appreciate the agency of people (read: live possibilities) is to watch closely how they survive, even in, especially in, their oppressed state (West 1989).

Du Bois’s multivocal craft deepened over the course of his life, and he was adept at picking up

and dropping ideas and practices as their real-life consequences became clear to him. Imbued with what Irving Horowitz referred to in another context as a “Jamesian heroic definition of self” (Horowitz 1983), Du Bois concluded that small bore social scientific research was not a strong enough solvent for the racism faced by the Black community in the USA and as a consequence of his tests of a number of proposals for reform, his responses changed. He thereafter devoted his life to political protest and he became an agitator for change. He was one of the founding members of the National Association for the Advancement of Colored People (NAACP) in 1909 and spent the rest of his life testing out and revising his ideas as the conditions warranted. His later work involved an examination of Black nationalist proposals and in 1947 he drafted an NAACP document that asked the United Nations to pressure the USA to acknowledge the rights of 14 million oppressed African American citizens. For this and other efforts, he was arrested in 1951 and charged with being an unregistered agent for a foreign power.

It is hard to imagine a better testament to the possibilities of Pragmatist Intellectual Craftpersonship than W.E.B. Du Bois. While Du Bois would no doubt have made extraordinary contributions to American democracy had he not studied with the Pragmatists at Harvard, it is hard to imagine that the trajectory of his craft would have been as open to experiment and revision over time as his clearly was. He was open to any proposal that was capable of surviving the harsh test of the political world in which he operated. And he exhibited the same confidence in self that James, Peirce, and Dewey all possessed. That the power apparatus in the USA rejected his proposals did not dampen his spirit or his willingness to imagine other possibilities for himself and other: “It was a bitter experience. . . but I did not break . . . I found new friends and lived in a wider world than ever before – a world with no color line” (West 1989).

C. Wright Mills (1916–1962) offers another model for Pragmatist Intellectual Craftpersonship. Mills was both a sociologist and a theorist of Pragmatist craft work. Studying as an undergraduate under some former students of

George Herbert Mead at the University of Texas, Mills deeply internalized the early Pragmatists’ substantive and methodological worldviews. His biographer, Irving Louis Horowitz, argued that Mills’s entire career as an intellectual and activist cannot be understood without grasping Mills’s commitment to the possibilities for democratic citizenship he learned from his study of the original Pragmatists (Horowitz 1983). Mills’s dissertation at the University of Wisconsin was an in-depth study of the thought of Peirce, James, and Dewey (Mills 1969). In addition to a contribution to the literature on the “sociology of knowledge,” Mills took from the work of the three founders of Pragmatism the conclusion that the future possibilities open to those interested in building a democratic society depended upon the capacity of that society to generate forms of belief and knowledge that could guide the dominant institutions and mold individual behavior in ways consistent with participatory democracy.

In the entry on Mills in the *International Encyclopedia of the Social Sciences*, Immanuel Wallerstein said of Mills’s Pragmatist commitments: “Mills was a utopian reformer. He thought that knowledge properly used could bring about the good society, and that if the good society was not here yet, it was primarily the fault of men of knowledge” (Wallerstein 1968). Fundamental to the realization of these democratic possibilities was the creation of citizens capable of understanding and analyzing their individual and collective experiences. Mills learned from James the importance of what Horowitz calls Mills’s “first-person-singular theorizing” (Horowitz 1983, 128). For Mills, genuine learning is and has to be firsthand experience as without this engagement all one ends up with is the kind of abstract formalism that Peirce and the other Pragmatists decried (Mills singled out for particular criticism the work of the day’s leading theorist, Talcott Parsons, for his “Grand Theory” aspirations). Mills’s critiques of mid-twentieth-century American sociology were personal, incisive, and far-reaching (Mills 1959). For Mills, the importance of grasping experience with one’s bare hands, and one’s brain – via the “sociological imagination” – was something that every citizen could and should

learn if he or she wanted to contribute to the building of an American-style democracy.

Echoing the Pragmatist Craftsperson's theme regarding the importance of focusing on future possibilities, Mills was convinced that then-current social science scholarship was failing in its mission to help citizens get properly oriented to modern life and its possibilities: "We do not know the limits of man's capacities for supreme effort or willing degradation, for agony or glee, for pleasurable brutality or the sweetness of reason. But in our time we have come to know that the limits of 'human nature' are frighteningly broad" (Mills 1959). Some of Mills's ideas from his 1959 book outlining the frame of mind needed for social analysis ("the sociological imagination") are excerpted or anthologized in many readers, but it could be argued that the core of his Pragmatist-inspired teachings as to craftpersonship have little penetrated even the sociological establishment, let alone the larger cultural environment. A few of Mills's ideas as to craftpersonship will be cursorily mentioned here as it might be argued that these suggestions point to creating precisely the type of craft sensibility needed in a world that seems to encourage hyperindividuality and expression without the vetting/sorting/disciplining effect that the Pragmatists argued was essential for the generation of potentially efficacious ideas, beliefs, and behaviors. Pragmatists of all flavors believe that building democratic forms of life require the encouragement of creativity, innovation, and change – collectively, "imagining the possible" – but they also believe that a capacity for hearing and being receptive to the suggestions and objections of others is essential in any viable form of genuine democracy. Mills shared James's pluralism and need for hearing other voices. Toward the end of his life, his work shifted in the direction of the cultural space that W.E.B. Du Bois occupied as activist and journalist when Mills traveled to Cuba after the Cuban Revolution. In *Listen, Yankee! The Revolution in Cuba*, Mills gave voice to some of the revolutionaries he personally interviewed, including Castro and Che Guevara (Mills 1960). Like Du Bois, Mills' work attracted the interest of the internal security apparatus of the USA and Mills was told of a plan in which he was

to be assassinated by American agents. Like Du Bois, Mill was undeterred (although he did sleep with a gun by his side thereafter. Not likely something most contemporary social scientists consider part of their job description) (Mills 2000).

The model of the Pragmatist Craftsperson laid out by Mills is only one suggested exemplar of this cultural type. But it is a powerful one. An argument could be made that Mills's Appendix to his 1959 *The Sociological Imagination* entitled "On Intellectual Craftmanship" is one of the most important documents in the history of contemporary Pragmatism. In it, Mills attempts what few other scholars have the courage (or perhaps capacity) to do: He pulls back the screen to show exactly what one practicing craftsperson does when he attempts to understand both his own experience and the experience of his fellow citizens (James does something similar in his *Talks to Teachers* in 1899). Originally written in draft form in 1952, Mills mimeographed his "On Intellectual Craftmanship" for his graduate students at Columbia in 1955. It was further revised for publication for his 1959 work (Mills 1959; Summers 2008).

In the original draft, Mills discusses why he decided to write the piece (Summers 2008). Mills reports that it is not a secret that most professors complain that students do not know how to do independent intellectual work. When Mills would suggest to his colleagues that the students might be taught to do so, he said he heard in response: "But... you can't just teach people how to think..." Mills observes: "There is the complaint and there are the dogmatic answers to the complaint, all of which amount to saying: 'But we cannot help them much.' This essay is an attempt to help them" (Mills 2008). In a response that echoes the Pragmatist, open spirit of critical inquiry of James and Peirce, when Mills is told by other professors, "'Well, that is the way you work, but it's not of much use for me,' Mills responds: 'Wonderful. Tell me how you work'" (Mills in Sommers 2008). Mills's chapter on Intellectual Craftmanship provides the methodological foundation for a thoroughly Pragmatist craft sensibility, offered in the same open and "sharing" spirit characteristic of the original Pragmatists.

Mills claims that it is the sociological imagination of the craftsperson that is "... the quality whose wider and more adroit use offers the promise that... human reason itself – will come to play a greater role in human affairs" (Mills 1959). Such is the utopian possibility offered by Mills's version of the Pragmatist Intellectual Craftsperson.

Richard Rorty (1931–2007), late University Professor of Humanities at the University of Virginia, was born in New York in 1931. After receiving his Ph.D. from Yale, he taught analytic philosophy at Princeton for 15 years before his interests shifted to a Pragmatist philosophical perspective. Rorty's interest in the Pragmatist tradition led him to the work of John Dewey whose experimental and democratic approach to philosophy and social issues of the day impressed Rorty. Rorty develops an historical narrative in which the twentieth century's long philosophical journey from the dispatching of idealism through logical positivism, analytical philosophy and its critics in linguistic philosophy and then postmodernism, ended up where it started, with the Pragmatists, in particular, with John Dewey.

Following Dewey, Rorty argues that contemporary intellectual work in a world many have defined as postmodern requires the experimental approach first seen in Dewey and the other Pragmatists who went beyond their generation's own version of what in later days would become the "foundationalism" of analytical philosophy. According to Rorty, Anglo-American analytical philosophy functioned as the philosophical PR (public relations) firm for most scientific work in mid-twentieth-century philosophical thought. Following the early Pragmatists, Rorty argues that building a just society open to not only current but future possibilities requires very little of the preliminary, abstract conceptual work characteristic of much of the Western philosophical tradition (Rorty 1989). Rorty argues that Plato's *Republic* set a bad example by promoting the notion that philosophers – or other exceptionally smart and/or well-trained types (like social scientists) – should sort out all the conceptual difficulties before going to work establishing a just society (Rorty 1982).

The type of post-philosophical craftsperson Rorty envisions is more poet than scientist, an "all-purpose intellectual" or at times, a "liberal ironist" who is comfortable reading across all the disciplines and forms of knowledge. More Dewey than Peirce (or even James), Rorty argues that a democratic culture needs to be "de-divinized" by thinkers and citizens comfortable with "grounds" no more certain than Socratic-like conditions of the free exchange of ideas, beliefs, and plans. Rorty argues that the possibilities for a truly democratic culture asks no more of its citizens than that they attempt to justify their proposals in open and democratic debate with others. For Rorty, one's very conception of what is possible in a truly democratic world depends on what one allows oneself to "hope" for and this is expanded greatly by the capacity to understand or "read" widely within and across the different individuals and cultures that make up our diverse social worlds (Rorty 1989, 2000).

Rorty concludes with the argument that we need to think a little harder about what it takes to build a democratic culture. He argues that it requires less talk about how one's claims are grounded in something larger than one's self, group, or local culture and more social experimentation without the expectation that this could ever result in universal agreement or Truth. For Rorty, it is enough that citizens attempt to win others over to their point of view through debate and compromise. To want more than this messy process of building "solidarity" is to want something that is less like a democracy and more like manipulative power politics.

Even if nothing else survives from the age of the democratic revolutions, perhaps our descendants will remember that social institutions can be viewed as experiments in cooperation rather than as attempts to embody a universal and ahistorical order. (Rorty 1991)

The Post-Rorty World

Critics of what some critics refer to as Rorty's "Neo-Pragmatism" come from many directions. Some, like Bernard Williams, come from within

mainstream philosophy (Williams 1990). Williams argues that in Rorty's desire to be a poet as a way to escape from the gravitational pull of "foundationalism," he floats off into a world of fanciful (im)possibilities and sacrifices what Williams claims were the quite legitimate "scientific" goals of Peirce, James, and Dewey. Williams and others closer to the "realism" of Peirce, including Roy Bhaskar (1990), the Peircean Susan Haack (2006), and the so-called "New Pragmatists" (Misak 2007), argue that Rorty throws the democratic baby out with what Rorty sees as dirty bathwater of science. They claim that Rorty misunderstands that science is the only cleanser available to human beings that recycles and renews itself as part of its mission to "get things right," not just generate poetical, theoretic possibilities without the disciplining effect that an exploratory science can – and did – bring to the original Pragmatists. Even the intellectually promiscuous William James thought that one could go too far in generating "possible worlds" and held some of Freud's claims about the interpretation of psychological symbolism to be "a most dangerous method," perhaps too far out for serious consideration (James 1935). In this vein, Charles Taylor argues that Rorty's Deweyan desire to simply "change the western philosophical conversation" that has been going on for several thousand years concerning what is real is a form of ignoring or losing sight of important lessons. Rewriting Santayana, Taylor says "...those who ignore philosophy are condemned to relive it" (Taylor 1990).

Rorty as Pragmatist Intellectual Craftsperson thus stands as one of the most impressive and important of exemplars of the depth and variety within the Pragmatist craft but certainly not the last word in terms of the how one might conceive the possible but also the limits to the possible. Recent work in "Experimental Philosophy" might be seen as the more legitimate heir to the Pragmatist tradition than Rorty's work in which the assertion that "The Poets win" in their contest with the Scientists is premature, if not anti-Pragmatist (Knobe and Nichols 2008).

Another post-Rorty extension is seen in the work of Charlene Haddock Seigfried in her 1996 *Pragmatism and Feminism: Reweaving the Social*

Fabric. Seigfried explores the neglected history of the works of women (starting with Jane Addams, whose work greatly influenced Dewey's ideas), and who were, by almost any measure, original contributors to, as well as influenced by, the early (and continuing) Pragmatist tradition. Seigfried's inscription to her 1996 book sets the substantive framework for her studies and it comes from a comment John Dewey made in 1919:

When women who are not mere students of other persons' philosophy set out to write it, we cannot conceive that it will be the same in viewpoint or tenor as that composed from the standpoint of the different masculine experience of things. (Dewey in Seigfried Seigfried 1996).

In her magisterial analysis, Seigfried concludes her study with a sophisticated coda of Feminist-Pragmatist Craftspersonship that joins the spirit of the open universe of possibilities with a critical collaboration called for by the early Pragmatists discussed here:

Feminist pragmatists try to figure out what mechanisms – social, institutional, educational, political, an cultural – open possibilities of consensual decision making and revisioning in light of desired, eventual, concrete outcomes and which ones preclude or diminish it. It is this instance of 'prioritizing actual over hypothetical dialogue' [quoting Alison M. Jagger] that distinguishes pragmatist feminism from most 'Anglo-American ethics.' Consensus does not mean avoiding conflict or denying differences. ... (Seigfried Seigfried 1996).

Summary

In his 2019 book, *This View of Life: Completing the Darwinian Revolution*, evolutionary biologist David Sloan Wilson argues that it has only been in the past several decades that the full import of Darwin's ideas for understanding human thinking, behavior, and culture has been recognized. Wilson argues that an evolutionary worldview provides the best practical toolkit for thinking about the human species and its future possibilities. He notes that in the period following the publication of Darwin's work in 1859, few people understood the signal importance of his ideas for the understanding of human behavior and culture as clearly as did the early Pragmatists. They were

the first to grasp that the ideas, beliefs, and plans of human beings were part of the “natural” equipment of the human animal and that these beliefs and their consequences in the human-constructed societal forms were complements to the eyes and limbs and large brains we all possess.

In this revolutionary conception of life, each individual human being is an experiment of nature and that as such, each person can potentially contribute to the increasing adaptive capacity of the species by leveraging his or her unique perspective of the world (or worlds, if we follow James’s lead). The Pragmatists saw in concrete existence and particularized experiences of individuals, possibilities for new ideas and innovative angles, for new behavioral strategies and plans for living life or for organizing ourselves collectively. Another way of saying this is that each individual is properly seen as a possible incubator for the creation of a possible but currently unimagined world or worlds. Helping individuals become those incubators is exactly what W.E.B. Du Bois, C. Wright Mills and the other craft-oriented Pragmatists have been attempting for the better part of a century and a half.

Analogy

Alessandro Antonietti

Department of Psychology, Catholic University of the Sacred Heart, Milan, Italy

Abstract

Analogy is based on a relation between a familiar domain (called “source”) and a new domain (the “target”). Such a relation enables people to transfer some pieces of knowledge concerning the source to the target so to lead them to manage the latter in an easier way because they can take advantage of what they know about the former. When a source-target relation is set, possible features of the unfamiliar domain are identified, and this allows individuals to deal with it in a productive manner. In the opposite direction, the understanding of the familiar domain changes because the analogy induces to discover unsuspected aspects of the source. The analysis of the cognitive processes underlying analogy showed that realizing the possible correspondences between the source and the target is the crucial step, which shares some features of the insight because the

awareness of the source-target connections occurs suddenly but not through the progressive identification of the correspondences. Individual differences in reasoning by analogy support this notion since logical-analytical skills do not correlate with the ability to reason by analogy, which instead is correlated to an intuitive-holistic style of thinking. Finally, the possibility to train reasoning by analogy is taken into account and tips for education are reported.

Introduction

Analogy is a thinking and communication tool through which a relation between a familiar domain (called “source”) and a new domain (the “target”) is set. Thanks to such a relation, some pieces of knowledge concerning the source are transferred to the target so to allow people to manage the latter in an easier way because they can take advantage of what they know about the former (Gentner and Smith 2012).

Analogy is concerned with the issue of the “possible” in two ways. First, if a relation between the source and the target is established, possible features or meanings of the unfamiliar domain are identified and this enables individuals to deal with it since they have some ideas about how it may be conceived. Second, once the relation between the source and the target has been detected, the understanding of the familiar domain changes because the analogy leads to look at the source from a different perspective and to discover unsuspected aspects, and so new possibilities are recognized (Gentner et al. 2001). To summarize, analogy makes familiar what is strange (the target) and makes strange what is familiar (the source) (Gordon 1961).

To give an example: During a lesson a child gets hurt. The teacher takes him to the school infirmary, a place where that child has never

been. When the child goes home, he tells his mother that in the morning he had been accompanied into the “ambulance-room.” Up to that day the infirmary was an unknown concept for that child. The strategy he used to face such an unfamiliar situation was to find an analogy with something which was familiar to him. Since he knew very well what an ambulance is (he had a toy ambulance), he found that it looked like the new room where he had been taken for the first time in his life: In the infirmary he saw objects that there were also in an ambulance and he realized that the function of the infirmary (the target) is similar to that of the ambulance (the source). On the opposite direction, thanks to the analogy he established that child improved his conception of the ambulance as well: by making the experience in first person of what a stretcher is (since in the infirmary he was made to lie on the stretcher) and why it has wheels and moveable side rails, the child comprehended the functions of these features of the stretcher which is inside the ambulance toy.

It has been noticed that in many disciplines the development of a novel theory or perspective depends on applying an analogy drawn from a different domain of knowledge (Gentner and Grudin 1985; Hesse 1966). This is a process of which artistic intuition, historical reconstruction, scientific discovery, and technological **invention** (see **“Innovation”**) – fortuitously or intentionally – take advantage (Boswell 1981). Analogies occur in everyday thinking (Lakoff and Johnson 1980) and are present early in development (Goswami 1992). Political and social discourses and judgments (Gilovich 1981; Spellman and Holyoak 1992; Seixas 1994), as well as advertising messages (Holyoak and Thagard 1996), are often based on analogies. Legal (Marchant et al. 1991; Sunstein 1993) and medical (Eva et al. 1998) decisionmaking is sometimes grounded on reasoning by analogy. Moreover, in ordinary language people make use of analogies when they try to explain something (for instance, how a machine works or how an object must be employed) (Boerger and Henley 1999), to express their own thoughts (Honeck and Hoffmann 1979; Ortony 1979), to communicate their emotions and feelings and even highly structured forms of thinking,

such as mathematical reasoning (English 1997; Vamvakoussi 2019), have analogical grounds. Thinking by analogy appears early in the child's development (Glady et al. 2017; Whitaker et al. 2018) and school instruction may rely on analogies because they allow to clarify concepts which are difficult to understand (Duit et al. 2001; Kolodner 1997; Thagard 1992) and are a potential mechanism for the development of ► **creativity** (Bruner 1964). In all these situations, mapping a situation onto another one permits one to identify a wider or deeper meaning in the former and to find an unsuspected meaning in the latter. In both cases, the result is that our understanding has changed because a possible perspective toward the old and the novel experience is assumed.

Because of the broad field of application of analogy, the basic cognitive processes which support it are worth investigating, by highlighting the main mechanisms which are involved. In addition, considering how the skills in reasoning by analogy can be enhanced is important as well.

Why Is It Difficult to Identify Analogies?

There is evidence that people fail to transfer spontaneously what they know about the source to the target if they are not instructed about the source-target relationships. In fact in several experiments participants, who were presented the source without having been informed about its relevance to the target (no-hint condition), transferred the principles embedded in the source to the target in a very low percentage, not significantly different from that recorded in control conditions where no source was given. Conversely, high percentages of transfer emerged when participants were told that the source might be relevant to the target (hint condition). Such a difference between the no-hint and the hint conditions occurred with various kinds of situations (Bassok 1990; Gick 1990; Gick and McGarry 1992; Needham and Begg 1991; Novick and Holyoak 1991) and was found in adults as well as in children (Chen and Daehler 1989).

In order to distinguish the mere activation of the source information relevant to the target from

relating such information to the target, a series of experiments were carried out (Anolli et al. 2001). In these experiments two basic conditions were designed: reminding and hint. In the *reminding* condition the representation of the source was activated immediately before the presentation of the target by inducing participants to retrieve the critical part of the source relevant to the solution of the subsequent task, with no cue about the connection of such information to the target. By contrast, in the *hint* condition participants, before the presentation of the target, were told that the critical part of the source presented earlier would be useful to address the target. Results suggested that the lack of spontaneous transfer does not depend on failures in the activation of the relevant source information. In fact, although people were invited to recall source information, they did not transpose it to the target in a significantly greater proportion than did those in the control group. Rather, only when subjects became aware of the relationship between the source and the target, they applied the principle embedded in the source to the target. Therefore, reasoning by analogy needs the awareness of the source-target connection and the mere activation of the source immediately before or during the target task has no effect in enhancing transfer unless it is accompanied by a hint which suggests to search for possible source-target similarities.

Phases of Reasoning by Analogy

There is a consensus that reasoning by analogy can be divided into the following phases (Pierce et al. 1996; Reeves and Weisberg 1994):

- The “encoding” of the source.
- The “retrieval” or “search” or “selection” or “access” phase, which induces individuals to recall a source relevant to target.
- The “mapping” or “use” or “applying” or “adapting” phase, in which subjects construct orderly correspondences between the elements of the source and those of the target to draw a conclusion.

The lack of spontaneous transfer in reasoning by analogy suggests that the crucial distinction is between the second and the third phases, namely, between the phase in which individuals access the source information and the phase in which they use such information to derive the conclusion about the target. It is possible that, even if the source information is accessed, subjects fail to transfer it to the target because they cannot map it appropriately to the target. Conversely, subjects may be able to apply source information to the target but cannot access such information during the task. In order for spontaneous transfer to occur, both processes must take place. However, even though accessing source information alone does not ensure a successful use of it, failure to retrieve previously experienced situations is considered the biggest impediment.

Retrieval is a controversial phase. After the encoding of the source, source information is to be present in the persons' mind when they face the target. Such an activation may be elicited automatically by stimuli embedded in the target setting or by an intentional search in memory. In any case, individuals must realize that the activated information can be related to the target task because such information may be useful. This may happen either as a consequence of events which produce such an awareness or as a consequence of an intentional selection of the activated source information in order to identify which elements are relevant to the target. When people have realized the source-target connection, they can map the source onto the target to transfer what is embedded in the source to the novel situation by means of matching operations. In conclusion, it seems that reasoning by analogy is not an automatic process, but it requires controlled attempts to relate the target to a source. In other words, the process in question implies top-down rather than bottom-up mechanisms. Transfer from the source to the target does not appear to be data-driven but needs the search for correspondences between them.

The third phase is problematic as well. It was maintained that in this phase the abstraction of a solution schema from the source and its mapping onto the target are involved (Novick and Holyoak

1991). More precisely, persons – while also retaining separate representations of specific information from the sources (Bernardo 1994) – derive a general schema. When faced with the target, they then apply the schema to the new situation. As far as the mapping phase is concerned, the process is usually conceived as follows:

- People grasp the correspondence between an element of the source and of the target.
- Then they find in the source a relationship between the previous element and a second element.
- Consequently, they map such a relationship onto the target.
- The result is that a second source-target correspondence is found.

This process continues in this way until the mapping is completed, namely, all the relevant correspondences are identified. In sum, mapping is conceptualized as an incremental mechanism which yields, through the addition of new similarities to those previously found, the gradual extension of the source-target similarities which at the end, through the complete source-target overlapping, leads one to apply what is known about the source to the target (Keane 1990).

Analogy Does Not Involve an Incremental Process

Holyoak and Koh (1987) argued that retrieval of analogies is based on the summation of activation resulting from multiple shared features. If the sum of activation exceeds some threshold, the representation is retrieved and it can be used for further processing, such as an explicit source-target mapping. According to these authors, retrieval by summation of activation can provide a general mechanism for flexible access to information in the memory that is related to a novel input. An activation model responsible for reasoning by analogy has been proposed also by Anderson (1993). In this perspective, transfer occurs when the strength of the activation of the trace of the

source is sufficiently high. In this case, information embedded in the source becomes so strong that it can be applied to the target. The question is the following: Do people actually reason by analogy through an incremental process as predicted by these models?

Introspective reports and thinking aloud data (Wedman et al. 1999) failed to support the alleged incremental nature of reasoning by analogy. Van Lehn (1998), by analyzing protocols of students engaged in physics exercises whose solution was suggested by previous analogous examples, found that skilled solvers did not proceed in a sequential, progressive way. A study (Antonietti 2001) showed that source-target correspondences were suddenly identified and individuals seldom transfer knowledge to the target by means of a systematic process. It was also observed that thinking aloud, a procedure that usually improves performance since it “imposes” a well-structured way of reasoning leading individuals to proceed step-by-step, fails to enhance analogical transfer (Neuman and Schwarz 1998). Finally, experiments, where the mapping process was monitored by means of the similarity-rating task, induced to cast doubts about the incremental nature of the mapping process since reason by analogy appeared to be not a continuous, but a insight-like process involving mental acts which allow one to perceive, at a given moment, the whole source-target correspondences (Antonietti 2001).

This conclusion is consistent with the investigation of individual differences highlighting that people possessing creative and insight skills – as well as intuitive-holistic, adaptor, and field-independent cognitive styles – perform better in analogy tasks than persons with analytical thinking skills and styles (Antonietti and Gioietta 1995). It can be conjectured that these styles play a role in two different steps of the reasoning by analogy. According to several authors (Clement 1988; Gentner 1989; Gick and Holyoak 1980), in the first step people derive the structural representation of the source and in the second step adapt this schema to the novel situation. Presumably, field-independent individuals are skilled in reasoning by analogy because they are facilitated in the first

step, that is, in the abstraction of the schema from the source context in which it is embedded. Adaptors tend to have good performance in analogical transfer because they are facilitated in applying the principles derived from the source to the domain of the target.

The overall picture that emerges from the abovementioned studies suggests that cognitive processes underlying analogy are insight-like processes. Evidence supports the notion that prefrontal cortex – which is the core neurobiological mechanism involved in analogy-making (Bunge et al. 2005; Urbanski et al. 2016) – plays a role in the restructuring or insight phase, namely, when individuals overcome the mental impasse which prevents them to find the relevant answer and a new perspective emerges. Aziz-Zadeh, Kaplan, and Iacoboni (2009) found that the sudden discovery of an unexpected meaning in verbal problems is associated to the activation of a neural network including insula, anterior cingulate, and right prefrontal cortex. A decreased alpha power in the right prefrontal region, indicating an increased cortical activity, was reported by individuals who reached the solution of a problem by restructuring it (Sandkühler and Bhattacharya 2008). Thus, it appears that prefrontal cortex is actually involved also in insight-like instances of reasoning by analogy.

Reasoning by Analogy Can Be Trained

Can the ability to think by analogy be improved? Some techniques – such as synectics (Gordon 1961) – have been devised to train to produce creative analogies in order to solve professional problems and also some computer-based instructional systems have been designed to enhance analogy-based learning (Reimann and Schult 1996). In school settings, programs aimed at leading students to learn by identifying analogies between disciplines have been implemented as well (Alexander et al. 1998). More precisely, Vosniadou and Schommer (1988) reported that presenting students with analogies in order to facilitate the learning of new matters is effective when there is a hint that induces subjects to map a

familiar situation (that acts as source) onto the novel situation (target).

The possibility to enhance reason by analogy in childhood was investigated in a test-retest study which involved 4- to 6-year-old preschoolers who were presented a set of analogical thinking tasks (Antonietti 2000). This battery of tasks was administered twice, with a 6-month delay. During such period children were assigned to one of three conditions, each involving some training (There was also a fourth condition – control – with no training). The training consisted of two weekly sessions of about 90 min. In each session a previously instructed teacher presented pupils with a part of a structured program aimed at enhancing analogical thinking. The material consisted of a series of short stories underlying the same structure, even if characters, places, and situations were always changed. Starting from this material, children were invited to find, analyze, complete, vary, or create analogies. Stories concerned different domains (historical environments, scientific topics, linguistic issues, and social problems) and the exercises performed by children activated different expressive codes (motor, pictorial, and verbal). Such activities were conducted differently according to the experimental condition to which pupils were assigned:

- *Text condition:* Children had to process analogies found within a story or to match different stories to identify similarities.
- *Real-life condition:* Children were hinted at processing correspondences between stories and everyday-life situations and had to reflect about such correspondences. Analogies were focused above all on practical aspects.
- *Socio-emotional condition:* Children worked on similarities between affective and interpersonal issues, involved in the stories and their own experience, and elaborated them according to a variety of suggestions.

Analyses carried out on each age level revealed that the text and real-life training conditions were the most effective for 5- and 6-year-old participants, whereas the socio-emotional training was the most effective for 7-year-olds.

Conclusions

Research supports the notion that reasoning by analogy is a multidimensional process whose components have different developmental trends because of the involvement of different general mental function (for example, abstract ► [intelligence](#), linguistic competence, and divergent thinking). As a consequence, a range of different skills must be trained.

Furthermore, thinking by analogy can be improved in regular school environments across the curriculum by involving teachers of different disciplines. Finally, the dimension which benefits mostly by the training is ► [creativity](#). If we train children to pay attention to analogies, reflecting about them, and re-elaborating them, we foster fluidity and flexibility in thinking. Children become more able to identify common aspects in different realities and to transfer ideas from a domain to another. This helps to think divergently, to solve novel problems, and to find plots to tell story (see ► [“Divergent Thinking”](#)). In other words, a general cognitive flexibility leads to see familiar things with new eyes and to face new challenging situations by applying schemata drawn from past experience.

Anchoring

Ineke Sluiter¹ and Miguel John Versluys²

¹Department of Classics, Faculty of Humanities, Leiden University, Leiden, The Netherlands

²Classical and Mediterranean Archaeology, Faculty of Archaeology, Leiden University, Leiden, The Netherlands

Abstract

Anchoring is a concept describing the process or activity through which relevant social groups connect what presents itself to them as new to something they deem familiar (Sluiter, *Eur Rev* 25:20–38, 2017). It enables people to perceive or construct forms of continuity within change, and it helps them to accommodate and absorb new inventions, practices, objects, or ideas. As such, it is a necessary ingredient of successful innovation processes. As we will argue, anchoring should be regarded as a precondition for imagining the possible, in that it provides the imagination with a starting point: the familiar (which often is the familiar past).

Anchoring can be positive, where a direct connection is established with something already accepted, already playing a role in society; or it can be negative, when a foil is used to identify what something or someone *is not* or *does not want to be*. It can take the form of a link with the past and the traditional, on which more below, or it can connect a new phenomenon in one societal domain to a familiar analogue taken from another domain. For instance, when young people are asked to contribute a year of community work to society, recourse is had to the familiar analogue with the military domain, where we know “compulsory military service”: this yields the anchoring expression “civilian service,” which directs the audience toward the imagination of a new possibility. It is the process of anchoring that makes the new imaginable. Anchoring often takes place conceptually through language and discourse (Sluiter, *Old is the new new*:

the rhetoric of anchoring innovation. The language of argumentation, Springer, Cham, 2020). In the example of civilian service, the category of “service” is borrowed from the military and accommodated to the new domain by the addition of the qualifier “social.” In order to imagine the possible, we do not create *ex nihilo*, but we take as our starting point a familiar anchor. Any theory or analysis of the Possible should therefore take anchoring practices into account.

Anchored imagination · *Adynaton* · Categories of change · Imaginary worlds · Development

Introduction

Anchoring is a concept describing the process or activity through which relevant social groups connect what presents itself to them as new to something they deem familiar (Sluiter 2017). It enables people to perceive or construct forms of continuity within change, and it helps them to accommodate and absorb new inventions, practices, objects, or ideas. As such, it is a necessary ingredient of successful innovation processes. As we will argue, anchoring should be regarded as a precondition for imagining the possible, in that it provides the imagination with a starting point: the familiar (which often is the familiar past).

Anchoring can be positive, where a direct connection is established with something already accepted, already playing a role in society; or it can be negative, when a foil is used to identify what something or someone *is not* or *does not want to be*. It can take the form of a link with the past and the traditional, on which more below, or it can connect a new phenomenon in one societal domain to a familiar analogue taken from another domain. For instance, when young people are asked to contribute a year of community work to society, recourse is had to the familiar analogue with the military domain, where we know “compulsory military service”: this yields the anchoring expression “civilian service,” which directs

the audience toward the imagination of a new possibility. It is the process of anchoring that makes the new imaginable. Anchoring often takes place conceptually through language and discourse (Sluiter 2020). In the example of civilian service, the category of “service” is borrowed from the military and accommodated to the new domain by the addition of the qualifier “social.” In order to imagine the possible, we do not create *ex nihilo*, but we take as our starting point a familiar anchor. Any theory or analysis of the Possible should therefore take anchoring practices into account.

Anchoring the Imagination of the New

Anything conceptually available, and thus familiar, can function as an anchor. This was understood also in Greco-Roman Antiquity (see under ► “Antiquity”). In describing various categories of change, meant as an exhaustive enumeration, Aristotle (384–322 BCE) implicitly assumes that all change is based on the transition from a status quo to a new situation: the actual and the potential, as he calls them. Change can affect the status quo in its existence, quantity (addition, subtraction: e.g., growing or shrinking), quality (e.g., being healthy or sick), or place (e.g., here, there) (see e.g., Aristotle, *Physics* 190b; *Metaphysics* 1069b; 1042a for health and sickness). In the later Greek intellectual tradition, this becomes entrenched as an influential fourfold division of categories of change: addition, subtraction, substitution, or permutation (where two items change order) (Desbordes 1983). Each time, change starts from a base that functions as the anchor: this anchor is the status quo affected by the different forms of change. The fourfold division defined options for stylistic variation and linguistic change (Usener 1913), but also for the imagination of possible changes in the natural world.

Various schools of ancient philosophy after Aristotle pondered the question of the imagination. The Epicureans started from sense perception and assumed that images such as that of a Centaur (a horse with the upper body of a man)

would somehow arise from the combination of very fine free-floating particles given off by a horse with those coming from a man (Long and Sedley 1987, Sect. 15D; Lucretius, *On the Nature of Things* 4:739–742). The Stoic philosophers also started from sense perception and the so-called “impressions” (*phantasiai*, not the same as our “phantasy”) made by the physical world on our sense organs (or arising in a non-sensory way, through thought). They are different from the *phantastikon* (“imagination”), which may produce “figments” (*phantasmata*), not actually caused by anything leaving an impression – in fact, they may occur in people who suffer from melancholia or are mad (Long and Sedley 1987, Sect. 39A–B). According to the Stoics, we are not at the mercy of impressions or figments, but are in a position to form judgments about them. The thought operations that we use are again related to the categories of change discussed above: we can conceive of giants like Tityos and Cyclopes by the operation of magnification, of Pygmies by diminution, of eyes in the chest by transposition (change of place), of a Hippocentaur (horse-man) by combination, of death by opposition (Long and Sedley 1987, Sect. 39D = Diogenes Laërtius 7: 53). Clearly the starting point (or anchor) for thinking of the one-eyed giant (the Cyclops), or the diminutive Pygmy is a human being. The anchor consisting in the familiar is the launch pad of imagination.

Anchored Imagination: Fictional and Fantasy Worlds

Such examples of “anchored imagination” can be illustrated from many other domains, ancient and modern. The genre of biographical fiction has been described in these terms by the Irish author Colm Tóibín. He uses the concept of anchored imagination in describing how the bare bones of the facts of someone’s life can be used as a basis to invest a story with emotions and feelings (Layne and Tóibín 2018). In further reflecting on the relation between facts and fiction, he then expands this thought to encompass

not just biographical fiction, but all fiction: “all fiction takes its bearing from things that have happened in one way or another,” he says, and “I am using facts as anchors” (Layne and Tóibín 2018, 161, 165).

The notion of “anchored imagination” is helpful in understanding other phenomena as well. It also applies to the imaginary and fantastical worlds that have been and are being construed in many if not all cultures and periods (Wolf 2018). They involve creatures and/or events whose existence and occurrence are “impossible” in our actual world. They are located in the “not here/not now,” and can be fitted out with imagined landscapes, histories, peoples, forms of government, languages, customs, and material cultures. However strange and astonishing such details may be, they are always anchored in the somehow familiar. This is achieved by various cognitive operations: the creation of analogues and reflections, oppositions, deviations, and transpositions into the transcendent and the supernatural. Imaginings of Underworlds and the abodes of the gods in various mythologies can similarly be regarded as constructions of imaginary worlds anchored in the reality of the culture producing them. And, interestingly, once a tradition of creating such worlds exist, new versions may be anchored in that very tradition itself of imagining imaginary worlds (Rogers and Stevens 2017).

Anchoring the Impossible: The *Adynaton*

In imaginary worlds, the *possible* is imagined and often transcended. If they still manage to offer the appearance of the real, this is because they use the familiar as the launch pad of imagination. However, many languages and folk traditions also like to imagine and play with the *impossible*, while expressly labelling it as such. Its use in ancient Greek and Latin literature has earned such figures of speech and thought the general label of *adynaton* (Greek for “impossible”; Canter 1930 provides an overview of its different uses in Greco-Roman Antiquity; Rowe 1965). The *adynaton* is used particularly in emphatic and

hyperbolic (self-)assurances that something undesirable will never happen, that it is in fact *impossible*, as in “this will happen when pigs fly,” i.e., never. The rhetorical effect is produced by evoking something “really” impossible (flying pigs). The most reliable anchor for the *impossible* is nature and its laws, which cannot be broken, but culturally entrenched phenomena that are considered unchangeable can equally be anchors for the *impossible*. Our earlier example “this will happen when pigs fly” is an expression of impossibility or inconceivability anchored in nature; “Hell will freeze over before this would happen” is anchored in our cultural imagination of Hell. These forms of hyperbolic expression occur frequently in high literature, sometimes in a whole series (“sooner A, B, and C will happen than x”). A striking example is provided by Euripides’ *Medea*, when in a choral ode the tragic chorus expresses its shock at seeing the impossible having come true: the moral status of the sexes has been inverted, in that the male hero Jason has proved to be faithless, while the female foreigner Medea seems to have the moral high grounds (Mossman 2011, 257; Canter 1930, 36). This virtually unimaginable situation is anchored in an inversion of the laws of nature and of the cultural order: “The streams of the sacred rivers are flowing uphill, and justice and all is turned backward” (Euripides *Medea*, 410–411).

Such seemingly impossible things coming true in an unexpected way and with a shocking result is a not uncommon narrative motif. Shakespeare’s Macbeth will have nothing to fear until Birnam forest comes to Dunsinane, say the witches. Forests are not in the habit of traveling. This prediction, then, anchors Macbeth’s faux sense of security in the natural order. However, when Macbeth’s enemy, Malcolm, orders his soldiers to break off boughs from the Birnam forest trees and hold them in front of them on their march, the people in Macbeth’s castle see the forest approaching their stronghold, and indeed Macbeth’s end is near. The seemingly impossible came through. The failure to imagine its possibility seals the usurper’s fate. Playing with *adynata* presupposes a notion of the possible and uses our experience of reality as an anchor.

Anchoring the Possible: Calibrating Past, Present, and Future

Anchoring the imagination of the possible is frequently predicated on a construal of the relationship between past, present, and future. In imagining the possible we temporarily leave the here and now of current experiences to explore and “play” with the past, the future and alternative spheres of influence in order to shape the present (Abraham 2020). Past and present provide (a semblance of) stability to the process of imagination, in their function as anchors and launch pads. The stability is apparent rather than real, since the present and our memory of the past are themselves also under constant construction and are the subject of competing forms of societal imagination and negotiation (Assmann 2011). A form of imagination is operative, then, even in our calibration of past, present and future in relation to one another: we construct narratives about their particular relationships. These narratives are not only used to underpin our understanding of the present; they also help us in projecting possible forms the future may take. The process of imagining new futures is stimulated particularly effectively through contact with different perspectives. Processes of cultural contact and globalization force people to confront alternative world views and perspectives and open up new forms of imagination. These in turn are triggers for development (Zittoun and Glăveanu 2018; Zittoun et al. 2020). Elsewhere in this volume we have illustrated how that process works for the period of Antiquity (see “► Antiquity”).

The past “is a social construction whose nature arises out of the needs and frames of reference of each particular present” (Assmann 2011, 33). This does not condemn us to “presentism,” which would presuppose an infinitely malleable past (Koning 2010, 9) – there are clearly stronger and weaker constructions of the past. However, it does mean that relations with the past are ambiguous by nature and can be understood as “enabling” or “disabling.” Either way, the past serves as a (construed) anchor, positively or negatively, for our

understanding of the present and the imagination of the future. In that sense, imagining the present or the future would be impossible without the past. The process of anchoring, forging the connection between the newness of the present and the future and the (perceived) familiarity of the past is central to how imagination works as a sociohistorical process.

Conclusion

The main thesis for which we have argued in this essay, is that every form of imagination needs a starting point or anchor: imagination is concrete. It is a situated, embodied process distributed across brains, bodies, and things (Barona and Malafouris 2021). Imagining the possible takes its starting point from a particular sociohistorical context filled with peoples, things, and ideas (for important examples and case studies, see Dijkstra 2020; Wessels and Klooster 2021). Constituting the present and imagining the future is thus simply impossible without the effort of calibrating the past in relation to them. The process of anchoring, therefore, is fundamental to what imagining is about (Fuentes 2020; Glăveanu 2021). Any theory or analysis of the Possible should therefore take the concept and practices of anchoring into account.

Acknowledgements This study was supported by the Dutch ministry of Education, Culture and Science (OCW) through the Dutch Research Council (NWO), as part of the Anchoring Innovation Gravitation Grant research agenda of OIKOS, the National Research School in Classical Studies, the Netherlands (project number 024.003.012) (see www.anchoringinnovation.nl). We would like to thank Rutger Allan, Caterina Fossi, and Koen Vacano for sharing their conference call (with literature) on fantastical worlds.

Anticipation

Roberto Poli

Department of Sociology and Social Research,
University of Trento, Trento, Italy

Abstract

Anticipation is the translation into action of what has been seen in the exploration of possible futures through forecast and foresight exercises; it can be viewed as the capacity to use the future in the present. The future can be exploited in the present only if the realm of reality is far from being a given – that is, completed – totality. As a consequence, the laws of sociology, psychology, biology, or even those of physics may change together with the maturing of their ontological conditions.

Keywords

Futures studies · Rosen · Bloch · Real possibility · Latency · Tendency · Utopia

Introduction

Anticipation comes in different guises. As a lay term it refers to all forward-looking attitudes and activities. As a technical term, it assumes two different meanings: as a distinct aspect of futures studies that extends beyond forecasting and foresight modeling and as the qualifier “anticipatory” in the expression “anticipatory systems” (for further details see the entries on ► [“Forecasting”](#), ► [“Foresight”](#), and ► [“Anticipation Systems”](#)). These two meanings of “anticipation” pertain to two different frameworks. As different as they are, I take care to identically define these two acceptations of anticipation in order to facilitate their mutual translation (Poli 2017a).

Anticipation occurs when the future is used in action. From this perspective, anticipation consists of two necessary but distinct components: a forward-looking attitude and the use of the former’s result for action. A weather forecast in itself

is not anticipatory in our sense. Watching a weather forecast and, as a consequence, taking an umbrella before going to work is instead an anticipatory behavior.

Anticipation’s two components are consistent with Rosen’s definition: “An anticipatory system is a system containing a predictive model of itself and/or its environment, which allows the system to change state at an instant in accord with the model’s predictions pertaining to a later instant” (Rosen 2012). As explained elsewhere (see the entry ► [“Anticipation Systems”](#)), the expression “predictive model” is too restrictive and should be substituted by an expression including both forecasting and foresight.

The anticipatory processes and models that allow the future to become part of actions in the present may be either internal or external to the anticipating system. Watching a weather forecast and behaving accordingly is to use an external model; actions taken on the basis of subjectively constructed psychological expectations are internal.

Internal anticipation is particularly important for understanding the anticipatory behavior of people, groups, organizations, and institutions. As significant as anticipation may be for action, no anticipation is a guarantee of success. Continuing with the previous example, taking an umbrella before going to work does not guarantee that it will rain. While anticipation helps to develop more sophisticated courses of action, and is necessary for understanding much individual and social behavior, anticipation is not always correct. First and foremost, anticipation is a feature characterizing the behavior of suitably defined complex systems.

The argument is that behavior is primarily anticipatory, while reactive behavior is only a secondary – albeit important – component of behavior. A system behaving in an anticipatory manner makes decisions in the present according to “anticipations” about something that may eventually happen in the future.

One of the key starting points for research on anticipation is the contention that the currently dominant theories of time and causation are unable to incorporate anticipation, they therefore require thorough revision.

Anticipation is a widespread phenomenon present in and characterizing most types of real systems. Life in all its varieties is anticipatory; the brain works in an anticipatory manner; the mind is obviously anticipatory; society and some of its structures are anticipatory; even non-living or non-biological systems can be anticipatory.

The Four Meanings of Anticipation

Each of the four levels of analysis composing Table 1, as discussed in the entry entitled ► “Fore-sight”, presents an aspect of the theory of anticipation.

Compared to the difference between forecasting and foresight, anticipation is a translation into action: a future exercise that does not translate into decisions and actions is a failed exercise. Compared to megatrends and explorations, anticipation is a generation and consumption of the future: the decisions and actions that we take increase or decrease the space of possibilities in which we can intervene (see ► “Forecasting”). With regard to risks and uncertainties, anticipation is a matter of ignorance: what we do not know is more important than what we know. Compared to complicated and complex, anticipation is considered as the ability to follow changes in the system, grasping in advance the moves and steps that it will make.

The World as an Incomplete Process

Anticipation as the translation into action of what has been seen in the exploration of possible futures through our forecast and foresight exercises can be viewed as the capacity to use the future in the present (Poli 2019). The idea of “using” the future or “working” with the future

raises various questions. Science is still dominated by the practice of looking back (at the data), thus observing the future only within the limits of extrapolations from the past (see the entry ► “Forecasting”). The transformation from science oriented toward the past to science oriented toward the future (Seligman et al. 2013), or the idea of exploiting scientific research to “generate future” (Gergen 2015), are themes undergoing development but still completely in the minority (Poli 2017a, 2019). Yet what matters is understanding that a proper inclusion of the future within science requires developing a new conception of science (Rosen 1991, 2012).

To begin understanding some of the changes needed, it is advisable to consider the ideas of the thinker who has conducted the most extensive categorical analyses of the future. The entire work of Ernst Bloch is devoted to the future, from the early *Geist der Utopie*, through his magnum opus *Principle of hope* (Bloch 1995), to the *Tübinger Einleitung in die Philosophie* (partially translated as (Bloch 1970) and *Experimentum mundi*.

From an ontological perspective, Bloch (as well as Hartmann, see (Poli 2012) frames ontological categories as neither the most universal predicates nor a priori functions of the intellect. Instead, ontological categories are modes of being, the innermost determinations of being (on categories as modes or principles of being see (Poli 2007, 2009, 2010, 2011a, b). Bloch adds that ontological categories are categories of the not-yet-being, because the main feature of real being is its openness to the future. Precisely for this reason, Bloch’s ontology can be termed the “ontology of the not-yet.”

Bloch’s main claim is that the realm of reality is far from being a given – that is, completed – totality. On the contrary, the real continuously unfolds, and it may well be that the true nature of the real has still to surface. Furthermore, the conditions making the true nature of the real possible may still be pending, in the sense that they may be still in formation. Bloch’s claim goes deeper than the idea that the true nature of the real is hidden, awaiting triggers to activate and make it visible. Bloch’s position is more radical

Anticipation, Table 1 The four layers of futures studies

Layer 4	Complicated	Complex	Anticipatory
Layer 3	Risk	Uncertainty	Anticipation
Layer 2	Megatrend	Exploration	Anticipation
Layer 1	Forecasting	Foresight	Anticipation

than this: it amounts to the claim that, at least in some cases, the conditions making the true real possible are still entirely lacking. From this point of view, the idea arises that the laws of sociology, psychology, biology, or even those of physics may change together with the maturing of their ontological conditions.

The “real” that interests Bloch most is the real of social and, secondarily, psychological being. While his categorical framework does not exclude the possibility that the conditions making the lower layers of reality possible may still be unfolding or under formation, Bloch’s interest is focused on the realization of human beings.

The World as an Experiment

As said, Bloch sees the world as an unfinished process, the main reason being that the processes that are the world continue to unfold. Precisely because the world is an unfinished process, it can be taken as an experiment – an *Experimentum mundi*, as the title of Bloch’s last major work reads.

Being in a proper experimental mode, it is still undecided whether the world will arrive at some positive outcome or end in disaster – at least for us. That is, the experiment that is the world may fail (again, for us).

Since the world’s horizon is still undecided, one may claim that: “the world itself is not yet at home.” On the contrary, the world is in a state of continuous tendency toward new horizons, even if these horizons are far from being crystal-clear, visible, or well-defined endpoints. The tendency toward a horizon shows that the processual unfolding of the world is neither random nor blind but includes a direction.

Latency, Tendency, and Horizon

In order to understand the ontological nature of the world, what matters most is the tendency itself, more than its starting and ending points. However, in order to determine the details of this ontology, a clarification of the starting and ending

points of the tendency is needed. In Bloch’s terminology, these are respectively called “latency” and “horizon.”

To understand this tangled situation, one needs an ontology of the not-yet, of being as processual, and therefore of being understood as an incomplete, still unfolding reality, indeterminate with respect to its endpoint, leaving room within its core (starting point) for entirely new determinations as well as for growing or maturing ones.

Real Possibility

The modal category of possibility thus moves to central stage. Possibility here is understood as “real” possibility and not merely as “conceptual” possibility. That is, real possibility is possibility grounded in the real processes of the world, and it is different from possibility as conceptual variation.

Following Aristotle, Bloch distinguishes between *dynamei on*, “possible being,” and *katà to dynatòn*, “according to possibility.” Possible being is wider than being according to possibility. One can understand possible being (*dynamei on*) as “possible in general,” while being according to possibility (*katà to dynatòn*) is what governs the passage from general possibility to actuality.

Bloch further distinguishes what is objectively possible from what is really possible. Objectively possible is everything whose occurrence cannot be excluded on the basis of the present, partial knowledge of its actual conditions. Instead, something is really possible when its conditions are not yet fully assembled within the object itself. This may imply that the said conditions are still maturing or even that they are still entirely lacking. Real possibility comes in different guises: as the initial not-yet, as partial conditioning, as subjective capacity, and as the sea of possibility surrounding existents.

Entities Are Categorically Open

The future as an ontological category makes sense only if entities are categorically open – that is to

say, only if new determinations can be superimposed on an entity's previous determinations. This means that the ontological nature of entities is not thoroughly established. New determinations can always appear. Entities are never totally given in advance, and they have some kind of tendency toward the future. Just as understanding the past often helps the understanding of actually given situations, prefiguring the future may also aid understanding of actually given situations. As a preliminary note, it is important to distinguish the problem of missing information (the entity is imperfectly or only partially known) from the problem of the entity's categorical openness, that is, conditions of the entity that have still to mature. The former is an epistemological problem and does not bother Bloch (or Hartmann for that matter). The latter is a truly ontological problem.

"Categorical openness" means that the entity is not maximally determined; some of its aspects are still hidden. Better some of its determinations may still be lacking. The difference is that hidden components are there, waiting for proper triggers to activate them. On the other hand, lacking components relate to incompletely present conditions and aspects. Their incompleteness may be ascribed either to still maturing conditions or to new conditions that may subsequently arise (Poli 2006b, 2011a).

Not-Yet

The future-oriented category of the not-yet is anchored in the processual nature of the world. According to Bloch, everything becomes. The not-yet is the direction, the goal toward which everything aims. A description of the present (or, for that matter, the past) state of the world which does not include its not-yet is defective. It lacks the most authentic dimension of being, its aspiration toward completion.

The processual basis of the not-yet means that the identity of entities is not present internally to them, and for this reason entities must go outside themselves. For the time being, let me note that the process of going outside to find one's identity requires a direction – but it does not have to be a

predetermined or a once-and-forever pre-established endpoint. On the contrary, the endpoint may be present generically, and, properly speaking, it may even not exist. Therefore, the endpoint is not an attractor, at least not an attractor in the sense in which the term is used in the theory of dynamic systems. The not-yet works as a pulling force taking everything out of itself, without, however, acting from an explicitly pre-given ending point and with a pre-established intensity. On the side of the entity, the endpoint is its horizon; the force is called latent or latency, as in the expression "the latency of things"; and the direction is tendency.

While the latency of things refers to the force driving them to acquire their true identity – to be what they will become, that is, the identity of becoming – the not-yet of things is precisely this identity as seen by the entity still lacking it. Modally, the not-yet is the real possibility of the thing, what the thing can really become. "Really" here refers to the conditions that make achieving given targets possible – respectively, impossible – where possibilities are concrete, partial conditions of realization.

Realizations depend on two series of conditions: possibilities, or active powers able to change things, and potentialities or the passive capacities that things have to be transformed. Real possibility – the category of categories, as Bloch says – is partial conditioning. These partial conditions are open to the future as anticipations of open possibilities.

Bloch's now is not the present. The now does not last; while the present lasts for a while, it corresponds to what has been called "thick present" (Poli 2011c). The present is more than an instantaneous now, because it includes the pasts from which it derives and the futures in which it enters. Moreover, presents can have different durations. As Bloch explicitly states, there is no univocal delimitation of the present. Entire years and even decades have been counted as presents.

The outward unfolding of things is centered on the process of becoming, not on its already realized outcomes. The new emerges in the now into the present; the present then is creative; it is the open frame where the new may unfold.

On the contrary, the past is closed, it has become. However customary, this description of the past is far from being complete. Presents have their futures, both as components of the presents themselves and as subsequent generated presents. When presents fall into pasts, the futures intertwined with them fall into the past as well. Memories of the futures locked into past presents can still ring out in subsequent presents. Past presents include different types of futures. Antiquity for the Renaissance was less “closed” than antiquity for the Middle Ages. The productive nexus between the present era and a previous era is always a nexus that includes the future that was embedded in the past era. In this sense, even archaic archetypes may continue to be productive, perhaps as fragments needing later integrations.

It ensues from these remarks that the logic of “before” and “after” does not capture time. Time is more than a linear series of chronometric moments. Apart from the nexuses linking past futures to present futures, temporalities also depend on the events in them, and these events are organized in levels of reality and their multifarious relations.

On distinguishing chronometric time and real time, the possibility arises of delays or accelerations of the latter with respect to the former. The real time of living or social beings may show their backwardness, their being left behind by the clock of biological or social history; or it can show their forwardness, their capacity to open new avenues and act as precursors (Poli 2017b).

Causality for Bloch is more than connection between completely determined events. The most interesting cases are those of causal nexuses in which one can intervene and thereby produce new effects. According to Hartmann’s ontological terminology, this is a case of “overforming.” While we cannot modify the laws of physics, we can exploit them for our purposes (e.g., building a bridge): physical causal determinations are overformed by our intentional determinations.

To be noted is that, together with Hartmann, Bloch understands causality as a creative process (Poli 2012).

Causes should not be confused with conditions. The latter have different degrees of maturation,

while the former do not. Something can be more or less conditioned. The claim that something is more or less caused makes no sense. Partial conditioning makes sense; partial causation does not.

Bloch distinguishes among law, tendency, and latency. Law is the realm of repetition; where law dominates, novelties are lacking. By contrast, tendency is openness to the new; it is the source of ontological creativity. Tendencies need subjective interventions. An interesting generalization of Bloch’s framework includes the idea of tendency as intervention by other levels of reality: that is, overformation of the lower levels by the higher ones. In this case, the interplay between law and tendency becomes the difference between determining processes operating within a given level of reality and determining processes among levels of reality (on levels of reality see Poli (2001, 2006a, 2007).

Finally, latency is the ground of tendency. The unfolding whole, the whole in movement, the whole together with its tendency, includes latency as the ground from which tendency arises. According to Bloch, latents are not entities; even less are they closed and hidden factors or components, things that need to be unpacked; nor is a latent a hidden force sleeping on a tensed spring that could be awakened by releasing the spring.

Latency is the way in which the still nonexistent aim manifests itself in the tendency. It is anticipation of the endpoint.

Horizon and Front

On subjecting the openness of entities to closer scrutiny, further categories emerge, the most important being those of horizon and front.

As we have seen, everything real, being temporal, tends toward something else. The concept of horizon – as opposed to the concept of boundary used to distinguish a system from its environment – precisely suits our purpose. As Luhmann notes, “the essential characteristics of an horizon is that we can never touch it, never get at it, never surpass it, but that in spite of that, it contributes to the definition of the situation” (Luhmann 1976).

The entity's horizon delimits that fragment of the space of possibilities whose conditions are maturing. As its conditions mature, the entity's horizon moves ahead. Without horizons, entities are dead. They may still continue along their trajectories, but no real novelty can ever appear: everything is forever fixed. Horizons have fronts – “areas” where novelties appear. The front is the growing, maturing, changing section of the horizon.

Authentic and Nonauthentic Futures

Futures can be either authentic or nonauthentic. Nonauthentic futures are repetitive futures, futures without novelties. According to Table 1, they correspond to forecasts, megatrends, risks, and complicated systems. Moreover, non-authentic futures arise as schemata, while authentic futures are embedded in dawning, unfolding events.

One of the major tasks of an ontology of the future is to provide guidance in distinguishing genuine from non-genuine futures, open from closed, and unadulterated from deceptive, adulterated futures. The latter comprise features such as repetition, forecast, megatrend, and risk. The former comprise novelty, foresight, exploration, and uncertainty. The terms in the two lists are counterpoints to one another: repetition against novelty, forecast against foresight, megatrend against exploration, and risk against uncertainty. This table of oppositions highlights the most important opposition between the models exploitable by futures studies.

Concrete Utopias

The main aim of Bloch's *Principle of Hope* is to develop the idea of “concrete utopia.” A utopia is said to be concrete when it is able to anticipate the not-yet-conscious and to use it within the not-yet-become that is latent in ongoing historical processes. Interestingly, however, Bloch turns the idea of utopia from a millennial-type change into a component of daily life. In this regard,

Appadurai notes that “Ernst Bloch's grand work on hope marked a transition in European social thought from a preoccupation with utopias, radical revolution, and millennial change to more nuanced engagements with hope as a feature of quotidian social life and with the conditions for its cultivation” (Appadurai 2013). In other words, Bloch distinguishes between utopia as focused on the endpoint and utopia as focused on everyday life, especially its most insignificant? aspects – which amounts to saying that the roots of the future are in the present, if only can we learn to see them and develop the capacity to use them.

Anticipation Systems

Roberto Poli
Department of Sociology and Social Research,
University of Trento, Trento, Italy

Abstract

Anticipatory systems are a class of systems broader than Newtonian ones. The move from Newtonian systems to Anticipatory systems entails giving full significance to the future. Put otherwise, Newtonian systems are a subclass of Anticipatory systems. To understand their differences, one can distinguish between what a system is *made of* (structure) and what a system is *made for* (function). The former attitude is isolative; the latter is relational. These

two different modes of analysis (through elements or through subsystems) generate two widely different frameworks because each function can be implemented by different structures and each structure can express different functions.

Introduction

Whichever idea of system one may adopt, it should be noted that all the languages used so far to construct systems have their roots in the mechanics of Newton (Rosen 1974). This apparently bold claim can be clarified by specifying the information needed to construct a (Newtonian) system. In so doing, one can see that all (Newtonian) systems require the specification of two different types of information:

- The *instantaneous state* of the system, i.e., what the system is like at any instant of time
- How the system *changes* state, i.e., how the system moves from present or past states to new states as a consequence of the forces imposed on it

Put briefly, instantaneous states involve the specification of state variables, while a system's changes involve the specification of that system's equations of motion. Input-output (IO) models (also known as black box models) are only variations of (Newtonian) models which do not challenge the above claim. Even if IO models do not have state descriptions, inputs can be manipulated, and for each input, the corresponding output can be observed. A straightforward translation into the Newtonian framework connects inputs to the forces imposed upon the system and outputs to states. Newtonian mechanics studies the ways in which states change when the forces are kept fixed. IO models study the ways in which changes in the forces influence the states of

the system. Therefore, “the two modes of system analysis, at first so different, are in fact essentially the same, and differ primarily in emphasis” (Rosen 1974).

For the purposes of this entry, to be stressed is that all Newtonian systems share the basic assumption that the dynamics of the system depend crucially on present and past states of the system. No future information is ever allowed to play any role whatever. Let us state it explicitly.

Main Assumption of Newtonian Systems: Never Allow Future States of the System to Affect the Present Changes of State

As far as physics is concerned, only present states and present forces are taken into consideration. On the other hand, biological, psychological, and social systems need to include also past states (memory) and often past forces. This is a first major distinction between physical (or non-living) and non-physical (or living) systems. However, the inclusion of memory, as relevant as it may be, is not sufficient for proper distinction between non-living and living systems. Memory-based systems are still Newtonian, i.e., mechanical, systems, while living systems seem to require something more.

What is eventually required is to add a second and deeper feature, the inclusion of future states. I shall call the systems that include past, present, and future states *anticipatory systems*. As before, let me state explicitly the main assumption of anticipatory systems.

Main Assumption of Anticipatory Systems: Future States May Determine Present Changes of State

As to be expected, the logic of Anticipatory systems is very different from the logic of Newtonian systems. Before entering into details, to be noted is that during the twentieth century, anticipatory theories were repeatedly proposed and in fields as different as physics, biology, physiology,

neurobiology, psychology, sociology, economics, political science, futures studies, computer science, and philosophy. For an overview, see Poli (2017a, 2019a).

To establish a provisional reference point, I shall start from Robert Rosen’s definition of anticipatory system: “An anticipatory system is a system containing a predictive model of itself and/or its environment, which allows it to change state at an instant in accord with the model’s predictions pertaining to a later instant” (Rosen 2012, pp. 8, 313, originally published in 1985). The expression “predictive model” covers the level of forecasts only (see the entries ► “Forecasting” and ► “Foresight”). As I have explained elsewhere, anticipation is not limited to forecasting models alone; it also uses both forecasts and foresights (Poli 2017a, 2019b).

The anticipatory processes and models that allow the future to become part of actions in the present may be either internal or external. Watching a weather forecast and behaving accordingly is to use an external model; actions taken on the basis of subjectively constructed psychological expectations are internal. Internal anticipation is particularly important for understanding the anticipatory behavior of people, groups, organizations, and institutions (Poli 2016).

A Model of Anticipatory Systems

Let me start from any whatever system *S*, which may be an individual organism, an ecosystem, a social system, or economic system. For simplicity, I assume that *S* is an ordinary (i.e., non-anticipatory) dynamic system. A second system, called a model *M* of *S*, is then associated with *M*.

The only preliminary condition I need to assume is that the dynamic evolution of *M* proceeds more rapidly than the dynamic evolution of *S*. In this way, *M* is able to predict the behavior of *S*. By looking at *M* we obtain information about a later state of *S*. So far nothing is really new.

The real novelty intervenes by assuming that *M* and *S* can interact with one another, i.e., that *M* may affect *S* and *S* may affect *M*.

Anticipation Systems,
Fig. 1 Basic components
 of an anticipatory system

The direction from S to M can be seen as an updating or improvement of M. This direction is rather straightforward, and I shall skip its analysis. On the other hand, the opposite direction from the model M to the system S is much more intriguing.

In order for M to effect S, M should be equipped with a set of effectors E, which allow M to operate on S (or on the environmental inputs to S) in such a way as to change the dynamics of S.

Figure 1 depicts in a hyper-simplified way (e.g., without considering either the environment or the upgrading of M) the logical connections between S, M, and E.

If we consider the three systems as parts of one single system, the latter will logically be an anticipatory system in which modeled future behaviors determine present states of the system. As Rosen said “M *sees* into the future of S, because the trajectories of M are faster than those of S” (Rosen 1974).

A simple question will aid understanding of the connections among M, E, and S: How can the information available in M be used to modify the properties of S through E?

The simplest answer is to divide the state space of S (and hence of M) into desirable and undesirable states. As long as the dynamics of M remain within the desirable region, no action is taken by M through the effectors E. On the other hand, when the dynamics of M move into the undesirable region (implying that the dynamic of S will later move into the corresponding undesirable region), the effectors are activated to keep the dynamic of S out of the undesirable region.

Rosen notes that “from this simple picture, a variety of insights into the nature of ‘planning’, ‘management’, ‘policies’, etc., can be extracted” (Rosen 1974).

Anticipatory systems can go wrong in different ways, which can be summarized under the three headings of:

- Bad models
- Bad effectors
- Side effects

A model can be bad for:

- Technical reasons (ignoring relevant state variables, wrong specification of the equations of motion)
- Selection of an incorrect paradigm (modeling anticipatory behavior by means of non-anticipatory models)
- Wrong correspondence between the states of system S and the states of the model M

Effectors can be bad because they:

- May be unable to steer S
- May fail to manipulate the variables of S appropriately
- May be programmed badly

The third family – the one called “side effects” – is definitely the most interesting case. The main outcome obtained on studying anticipatory systems is that side effects are *inherent* properties of the framework. Side effects arise even if the model M is perfect and the effectors E are perfectly designed and programmed. Even if everything is perfect, there will always be unintended consequences.

Side Effects

Side effects (or unintended consequences) are a structural feature of anticipatory systems. By default, when the system S carries out a particular activity A, S uses only some of its internal

resources. Technically speaking, S uses only some of its degrees of freedom.

In more intuitive terms, organizations (systems) are such that for them the same internal structure is usually involved simultaneously in many different functional activities. Side effects are due to the tension between the fact that (1) the equations of motion of a system S link together all the variables defining S, while (2) the variables not involved in a particular functional activity are free to interact with other systems in a non-functional (eventually dysfunctional) way (Rosen 1974). As a consequence, all the functional activities of a system S are prone to be modified or lost over time.

It is interesting that, given a system S, any functional activity A of S can be modeled by a model simpler than the model of S. The reason is evident: the model of A does not include all the variables of S but only those relevant to the selected activity A. As a matter of fact, Rosen notes that “it is largely because of this property that science is possible at all.”

On the other hand, no model whatsoever has the capacity fully to capture the potentialities of a system S for interactions with arbitrary systems, because any interaction is specific (i.e., a functional activity). Except for simple systems, no model can represent all the system’s relevant properties and/or interactions with other systems (Rosen 2012).

A major consequence of the theory is that effectors E will in general have effects on a system S other than those which are planned. Side effects are a general property of anticipatory systems, and there is no general way to get rid of them.

Back to Systems

The move from Newtonian systems to Anticipatory systems implies giving full importance to the future. Anticipatory systems are a class of systems broader than Newtonian ones. Put otherwise, Newtonian systems are a subclass of Anticipatory systems. This is a major issue because it changes our idea of science (Poli 2017b). To understand at

least some of the implied issues, let us resume the idea of “system.”

As well-known, the official founding father of the theory of general systems is Bertalanffy (1968, 1972). There were a few preliminary works in the field of general systems theory before Bertalanffy. In this regard, from a philosophical point of view especial mention should be made of Hartmann and Whitehead (Hartmann 1912; Whitehead 1967). The basic ideas of the theory are spelled out in Bogdanov’s *tektology* (Bogdanov 1984), an early Russian version of systems theory. Other early developers of a systemic perspective were Lotka and Koehler (Koehler 1920; Lotka 1925).

To grasp the novelty of the systemic position, consider the principle of composition, one of the fundamental assumptions of classical science (Poli 2017a). According to the principle of composition, an entity under investigation is decomposed into parts. The idea is that the entity is made of these parts so that decomposition into parts eliminates no relevant information. This assumption is universally valid, provided that the following conditions are fulfilled: (1) the interactions among the parts do not exist or are negligible, (2) the relations describing the behavior of the parts are linear, (3) the whole resulting from the parts does not engage in any functional behavior. These are very severe restrictions, however; very few if any natural systems comply with them. Systems in general do not fulfil these conditions. The parts of a system are in interaction, their relations in general are non-linear, and systems are encapsulated within other systems. One may describe the difference between the two cases as the difference between not organized complexity, well-represented by classic physics, and organized complexity, well-represented by biology (Weaver 1948).

Fundamental for organized complexities is the concept of hierarchical order, according to which systems are decomposable into sub-systems and these into further sub-sub-systems.

Note that the starting point of this new conception is the system (the whole) and that systems are decomposed into sub-systems, not into elements or atomic components.

In the same manner that the Copernican revolution was far more than the ability to calculate the movement of the planets better, and relativity has been much more than an explanation of a small number of recalcitrant physical phenomena, the introduction of system theory is more than the study of nonlinear dynamics.

Two Kinds of Analysis

How should one study a natural system? As said above, the usual strategy is to break the system down into its constituent elements. If the resulting elements are still too complex, the same procedure is repeated until the analyst arrives at elements simple enough to be understood. Ideally, once the “elementary” elements or particles have been found, the original system can be reconstituted from them.

This strategy hints at Descartes’ methodological rules. The implicit assumption is that all the relevant properties of a system can be recovered by taking its elements and their relations into account. This divide and rule strategy has proved immensely successful. The problem, however, is that some systems cannot be fragmented without losing information (Poli 2017a). The simplest reason is that there are systems for which the analytic strategy of breaking them down into elements without losing information does not work properly. More than this, systems which are entirely governed by their elements (as well as those entirely governed by their past) are rare. The vast majority of systems exhibit a different pattern: they depend not only on their elements but also on the system that results from them, and eventually also on higher-order systems of which they are parts (e.g., organisms, communities).

A promising strategy is to distinguish between what a system is *made of* (structure) and what a system is *made for* (function) (Rosen 1971). The former attitude is isolative; the latter is relational. The distinction is therefore introduced between two different modes of *analysis*: the analysis of a system into its elements and the analysis of a system into its subsystems.

One should be careful to avoid the assumption that each functional activity implies a given structure that supports it. In fact, the relation is far from being one-to-one; instead a many-to-many relation is implied, in the sense that each function can be implemented by different structures and each structure can express different functions.

An example may help. Consider a particular company. To survive and develop, the company should perform a variety of different functional activities, including the design of new products, producing, storing and circulating them, managing employees and workers, etc. Any of these activities may be performed by a specialized unit, or they may be split among a variety of units in many different ways. Companies make different choices in this regard. All the possibly different structural choices notwithstanding, the functions to be performed are analogous. Structures divide; functions unify (Poli 2017a).

One of the major differences between analysis via elements and analysis via subsystems is the following: given a system S , there is only one maximal set of component elements, while there are many ways to decompose the system S into functional subsystems, both at different hierarchical levels and from different perspective points.

To compound the problem, the functional perspective is not limited to the subsystem/system relation. The system itself enters into functional relations with its environment or, better, with other systems in its environment. And, as the case may be, it can establish different functional relations with different systems. Moreover, different functional subsystems can develop different functional relations among themselves. The social realm furnishes numerous pertinent examples: one may consider functional subsystems such as the economic, political, legal, scientific, etc. ones and the network of their functional interdependencies.

The availability of different kinds of analysis (and, possibly, different kinds of synthesis) shows that different strategies can be used. It is therefore important to understand the strengths and weaknesses of each strategy.

Complicated and Complex

The two forms of analysis distinguished above underlie the difference between complicated and complex: complicated systems are understood through *structural* decomposition, i.e., through the segmentation of the system into disjointed structural parts and the relationships that connect them. If a part is still too complicated, it is further divided into even smaller parts and their relationships. Complex systems, on the other hand, are understood through a *functional* analysis, that is, through the *activities* exercised by the system toward other systems at the same level or a superior level. Structural and functional analyses can only be coordinated in very special cases. In general, however, their results are different and their correlations are anything but trivial (both conceptually and mathematically) (Louie and Poli 2011, 2017).

Natural systems (including social and psychological systems) have a finite number of structural parts; on the contrary, the functions that those systems can perform are potentially unlimited. The main way to limit the set of functions that a system can perform is to add constraints to its environment, for example, by allowing the system to interact only with certain other types of systems. This means that functions can be limited by closing the system (eliminating interactions with other systems) or by closing its environment (allowing only specific interactions).

The third difference between complicated and complex systems is the extent to which they can be represented by models. Complicated systems can, at least in principle, be fully understood and modeled, i.e., they can be fully captured by appropriate models. Although the implementation of these models can be (and often is) partial, for example, because of a lack of data or because the development of a complete model is too expensive, these are purely contingent obstacles. In principle, it is always possible to build a complete model of a complicated system. Complex systems, on the other hand, can never be completely captured by any model. The models that depict them, even in principle, are always incomplete and diverge over time, i.e., they

gradually lose the ability to grasp the dynamics of the system that they should represent.

About Houses and Cats

The difference between complicated and complex can be described in many different ways (which, in turn, is a characteristic of complexity). Perhaps the most intuitive version is the one that distinguishes complicated systems from complex ones on the basis of two different meanings of the whole-part relationship.

Consider the structure of a house. A house has several structures that are part of the whole: on the one hand, it can be divided into the materials that compose it (bricks, pipes, wood?, etc.); on the other hand these same materials are organized in such a way as to produce functional units (kitchen, bedroom, living room, etc.). The critical point is the priority of the parts over the whole. The house is the product that results from appropriate amounts of materials, properly organized.

Let us now consider a cat. Cats are not produced in the same way as houses. Their production does not start with appropriate amounts of materials which are then assembled. Eventually, since the fecundated ovum, a cat is already a whole. All parts are produced by the whole, and all internal differentiations are produced by the whole. If certain minimum conditions are met (food and air, for aerobic organisms), everything else is produced internally. In this case the whole prevails over the parts.

Obviously, we could analyze the cat in the same way as we analyze the house, decomposing the whole into different types of parts; but it would be as if we were taking a picture and transforming the underlying generative processes into a static image. It is the same logic that is valid between local simulation of single aspects (the point of view of complicated systems) and processual modeling of the whole (the point of view of complex systems).

The systems that operate in the two cases are radically different. In the first case, these are systems that can be understood by analyzing their different parts and the way in which they behave.

The *feedback* cycles of *system dynamics* are perhaps the best-known version. In the second case, however, the recourse to *system dynamics* corresponds to the adoption of a reductionist viewpoint that forcibly translates complexity into complication.

²Department of Classics, Faculty of Humanities, Leiden University, Leiden, The Netherlands

Abstract

This essay presents conceptualisations of the Possible as they were developed in “(Classical) Antiquity.” This period is defined as encompassing the history of the Greek and Roman civilizations in their Mediterranean and Eurasian contexts between approximately 500 BCE–500 CE (Naerbout and Singor 2014). First, we provide a general overview of how people in Antiquity coped with the uncertainty of future possibilities, which was mainly through divination, ritualized procedures for seeking knowledge of the (immediate) future. Secondly, we discuss how the horizon of the Possible was expanded during this period through increasing connectivity (Globalization). This facilitated a new role for imagination as part of social life as there was now more “Other” to imagine than (ever) before. We argue that paying attention to the (deep) past of socio-cultural concepts like the Possible matters greatly for two main reasons, one methodological and the other ontological. The ability to move between “what is” and “what could be” has been shown to be an important constituent of the human niche. A deep history of the Possible therefore provides a way to investigate the development of human

imagination. The other main reason to argue for a deep history of the Possible is ontological, in that it focusses on future-oriented activities in past societies with their specific worldviews, which produce and define specific conceptualizations of the future. However, *their future* may not be the same as *our past*. Our own specific ontology, our philosophy of existence, heavily influenced by Modernity, is thus put into perspective.

Antiquity (Greco-Roman) · Divination · Imagination · Globalization · Anchoring

Introduction: Toward a Deep History of the Possible

This essay presents conceptualisations of the Possible as they were developed in “(Classical) Antiquity.” This period is defined as encompassing the history of the Greek and Roman civilizations in their Mediterranean and Eurasian contexts between approximately 500 BCE–500 CE. First, we provide a general overview of how people in Antiquity coped with the uncertainty of future possibilities, which was mainly through divination, ritualized procedures for seeking knowledge of the (immediate) future. Secondly, we discuss how the horizon of the Possible was expanded during this period through increasing connectivity (Globalization). This facilitated a new role for imagination as part of social life as there was now more “Other” to imagine than (ever) before. We argue that paying attention to the (deep) past of socio-cultural concepts like the Possible matters greatly for two main reasons, one methodological and the other ontological.

Like us, people in the past were intensively engaged with “that which is not yet there” (Glăveanu 2021). Within the disciplines of Future Studies and Possibility Studies, however, relatively little attention is paid to constructions of the future and imaginations of the Possible in past societies. If a historical perspective is taken at all, it often goes back only a few centuries in time, with a preference for studying the “science fiction” produced in the past few centuries. It seems

that a deep historical perspective is lacking altogether, something that Jack Goody (2007) has, in more general terms, characterised as “the theft of history,” the blinkered view of the past that tends to obscure contributions from other cultures and deeper pasts than Western-European modernity. There is thus too little attention for how, in the past itself, past, present, and future were calibrated in relation to each other – and how this might affect us today. This is problematic because the ability to move between “what is” and “what could be” has been shown to be an important constituent of human evolution and the human niche (Fuentes 2020). A deep history of the Possible is therefore needed to properly investigate the evolution of human imagination (Koukouti and Malafouris 2020, who characterise this as an anthropological approach). Such a historical perspective will underscore and make more explicit to what extent “engaging with the Possible” is a situated, embodied process distributed across brains, bodies and things (Barona and Malafouris 2021). This lemma, of course, only provides an initial step toward such an ambitious project.

The other main reason to argue for a deep history of the Possible is ontological, in that it focusses on future-oriented activities in past societies with their own specific worldviews, which produce and define specific conceptualizations of the future. However, *their future* may not be the same as *our past*. Our own specific ontology, our philosophy of existence, heavily influenced by Modernity, is thus put into perspective.

This is to say that a deep history of the Possible could help us to overcome teleological ideas of temporality as if *their future* (in the past) could only lead to *our past* and present (Simon 2018). *Their future*, in other words, might not be the same as how we reconstruct it now, from our own specific ontology, in terms of *our past*.

Imagining the Future in the Ancient World: Divination

Imagining the Possible and developing knowledge of the future often requires external input from specialists. In Antiquity this input was

actively looked for and applied. It is therefore not true, as general accounts sometimes maintain, that people in the ancient world would feel powerless and in the grip of an inescapable fate (rightly Beerden 2013, p. 195): instead, they actively managed their future and thus imagined the Possible. For Roman society in particular, Dennis Feeney (2007) has remarked (with reference to the highly developed social and technological organization of Roman time structures) that “Roman time” was highly sophisticated and, in fact, less different from our “modern time” than often thought. We argue that the same is true for strategies of imagining the Possible in Antiquity.

Divination, the acknowledgement and semiotic interpretation of signs thought to have come from the supernatural, was probably the most important of these strategies and pervaded daily life in the ancient world (Sluiter 1997, pp. 163–168). Based on the idea of a particular connection between past, present and future, divination served to manage uncertainty and to imagine the future (Beerden 2013). In the Greek world, the practice of divination mainly consisted of oracular pronouncements about the future through the interpretation of the flight of birds, sacrifices, dreams or omens (Bremmer 2006). In a Roman context, divination was institutionalised and developed into “the science of future events” (*scientia rerum futurarum*), or at least that is how Cicero defines it in his book on the subject entitled *De Divinatione* (On Divination) (1,1). The Romans expected seer specialists like the *augur* (a birdwatcher) or the *haruspex* (a seer specialised in inspecting the entrails of a sacrificial animal) to be able to extract precise information about possibilities in the future (Briquel 2006).

Imagining the Longer-Term Future

The temporal range of divination as a practice seems to have been rather limited: stretching from the recent past to the (very) near future (Beerden 2013, p. 187). However, there certainly were forms of imagining the extended and unlimited future (for the question of the existence of the idea of Utopia in Antiquity, that we will not deal

with here, see Elsner 2021). The first way of doing so may be called analogical in the sense that experiences from the past were understood as something of a precedent for the (long-term) future. This is what the orator Lysias (around 400 BCE) expresses when he states (*Oration* 25, section 23): “you ought therefore, gentlemen, to take the events of the past as your example in resolving on the future course of things.” The kind of analogical thinking involved in this process is an example of “anchoring innovation” (Sluiter 2017; see “Lemma Anchoring”). A second example of imagining the longer-term future comes from literature and revolves around memory: it concerns the anticipation, by literary authors, of how future generations would remember them and their subjects. This way of thinking about the Possible and the future is to be found from our oldest poem, Homer’s *Iliad*. Homeric heroes greatly valued their *kleos*, their reputation as it was laid down in epic poetry that would be sung forever (Nagy 1979; Segal 1994). In fact, the memory of future generations would guarantee their “immortality.” A hero like Hector hopes – and thereby anticipates the possibility – that future generations will say of his young son: “he is even better than his father” (*Iliad* 6.475–481). He also proposes, in preparing for a duel with a Greek hero, that if he wins, he will return the body of his opponent to the Greeks for burial and imagines the effect on future generations: “One day, someone will say, one of the people coming after us [. . .]: ‘There is the grave of a man who died long ago, an excellent man whom the radiant Hector killed.’ So they will say one day, and my fame will never die” (*Iliad* 7.87–91). In general, ancient authors have a strong sense of the future survival of their work. Thucydides (fifth to fourth century BCE) calls his *History* a “possession for all times” (*ktêma es aei*, *Histories* 1.22); the Roman poet Horace (first century BCE), in speaking of the poem in which he commemorates a Roman politician, claims to have erected a monument “more durable than bronze” (*exegi monumentum aere perennius*, *Odes* 3.30.1) and adds “Not all of me will die” (*non omnis moriar*, *Odes* 3.30.6). The ancient future, therefore, was “open-but-not-empty” (Beerden 2013, p. 222; for teleological

historical narratives as a means to get control over (future) time, see Grethlein 2013).

Fate, Predestination, Free Will

Future-orientedness is also connected with concepts like fate, predestination, and free will, as they function in the ancient world. What do these notions, mainly debated within philosophy at the time, tell us about ancient ideas about the Possible? Already in Homer there is a multitude of names (*aisa*, *moira*, *nemesis*) for the power of fate. These are not seen as personal deities but rather as concepts to explain inescapable events (Frede 2006a). In Latin, the main term for this is *fatum*, the root of the modern English word fate. Antiquity had various theories concerning the issue of predestination, which is the conflict between the omnipotence of the divine – and thus the predetermination of the future – and individual free will. Stoicism posits the idea of a divine *logos* as the foundation of the *kosmos* with time becoming a causal chain. Platonism changes this by maintaining that we live *within* fate but not *by* fate (Graf and Drecoll 2006). Ideas on free will were therefore ambiguous and in fact often part of philosophical debates on the conflict between rational reflection, on the one hand, and non-rational desire on the other (Frede 2006b). In Greek, there is no concept of free will as an autonomous mental readiness to act, although the notion of *prohairesis* “choice,” comes close. The Latin *voluntas* seems to move even more in that direction. Be that as it may, it was not possible for anyone in Antiquity to imagine a motto like that accompanying Zack Snyder’s 2021 (uncut) movie-series *Justice League*, which seems characteristic of our twentieth/twenty-first century modernity: “Make your own future. Make your own past. It’s all right now” (https://www.youtube.com/watch?v=yZXRN_BINa4).

In an article provocatively entitled *Did the Romans have a future?*, Brent D. Shaw (2019) argued that “the Roman future” was much more limited and less complex than our modern imagination. The Romans certainly had ideas about future action however. Perceptions of storage

and its techniques – which were rapidly changing in the Roman era because they, quite literally, enabled a lot more future possibilities – are an illustrative example (Van Oyen 2020). However, Shaw (2019, p. 7) states, there is “nothing that can be identified as constructing the coherent interlinked thing that we call ‘the future’.” Acknowledging the coherence, complexity and extensiveness of Roman future-thinking in relation to other (historical) examples – “although still without *the* future of modernity” (Shaw 2019, p. 22) – he, in fact, reaches the same conclusion as Feeney did when investigating “Roman time” (see above): it was highly sophisticated and, in fact, less different from our “modern future” than often thought (now also Price and Berthelot 2020 with many examples).

The Possible, Imagination and Globalization in Antiquity

The reason why “Classical Antiquity” represents an important threshold in the evolution of human imagination and a deep history of the Possible is that the horizon of the Possible was expanded to include the whole known world during this period. Thus, the increasing connectivity (Globalization) that characterised Antiquity led to new forms of imagination in social life and resulted in the emergence of cosmopolitanism. As far as we can tell, this may have been the first time in human history that this happened in this particular form (Pradeau 2015; Stuurman 2017). Globalization, which can be defined as complex connectivity leading to time-space compression, is not only characteristic of Modernity but has a deep history and proliferated during the period of 500 BCE–500 CE (Pitts and Versluys 2015; Versluys 2022a). There is, moreover, a strong link between imagination and Globalization. Indeed, as Arjun Appadurai (2001, p. 14) states, Globalization “(–) is marked by a new role for the imagination in social life.” While the cultural nature of human experience and social life is not contested, recent research in sociocultural psychology shows that imagination is a situated, embodied process (Koukouti and Malafouris

2020; Zittoun et al. 2020). The question then arises what we can say about imagination as a situated process in Antiquity, focussing on its relation to Globalization, and how this impacted ideas on the Possible.

Differences between the Self and Other are at the very heart of the Possible, as it is the Other that allows the Self to imagine other possibilities. It is only through the Other that the Self is able to acquire new perspectives, that is: the different kinds of relations that we establish with the world in order to act within and in reaction to that world. As Vlad Glăveanu (2021, 20) put it: “(–) difference is the ontological root of the Possible as there would be no sense of possibility in an undifferentiated universe. In particular the differentiation between Self and Other opens up multiple ways of seeing things and of being in the world.” This was illustrated as early as 1744 by Giambattista Vico in his famous *Scienza Nuova*. Vico has human evolution on earth begin with giants, the first inhabitants of the earth, who live in the woods, underneath the trees, and are therefore unaware of the existence of the heavens. When lightning strikes, an open space in the canopy is created: a *lucus* according to Vico, which tellingly means both “a place where the light comes in” as well as “eye”. This changes the history of the giants fundamentally. They are no longer alone: they themselves now see the sky and, for the first time, can imagine a different world. It is only through a confrontation with the heavens, therefore, that the giants are able to see themselves and imagine a novel future; they soon start cutting the trees around them, building the first huts, then whole villages, etc. The redefinition of Self (earth) through Other (heavens) by imagining a different relation to the world is what puts history in motion, according to Vico (for this example and its interpretation we follow Safranski 2003). It is in this sense that novelty is bound to emerge when different perspectives are brought into dialogue: the Possible resides in the encounter (Glăveanu 2021, 4). The Other, therefore, is an action-orientation (so already Kristeva 1991). To manage this dialogical encounter, processes of “anchoring” are fundamental (Sluiter 2017; see section ► “Anchoring”).

Imagination prompted by outside perspectives, therefore, is at the very heart of human social life. It is subsequently developed and becomes more complex through time (Zittoun and Glăveanu 2018). The first *lucus* of the Giants, so to speak, would almost automatically be followed by many more “eyes” that enabled them to see and develop ever different perspectives on being within the world. This is how imagination leads human development. A robust imagination would have been a cultural asset, and indeed people invested heavily in it, through the development of (information-rich) communication systems and the manipulation of extra-somatic ecologies and materials “in order to imagine.” The period of Antiquity represents an important phase as part of the trajectory of the growing complexity of imagination practices and devices because of the fact that there were now more Others and more other perspectives available than (ever) before. Let us very briefly characterise some of the major developments for our period.

Although human history is characterised by connectivity from its earliest beginnings, the period around 1500 BCE witnesses a major proliferation of networks and systems of connections all across Afro-Eurasia (Versluys 2022a). The direct linkage between and among regions now became so frequent that many scholars consider the middle of the second millennium BCE to be the starting point of ancient Globalization (Sherratt 2017). In this period, imagination was probably mainly triggered by things that were introduced from the outside, because objects travelled more widely and in greater quantities than people did. In terms of the situatedness of imagination (Koukouti and Malafouris 2020) this is a clear example, then, of its material dimension (see Pitts and Versluys 2021 for objectscales). The circulation of goods characteristic of the Bronze Age is followed by an ever more intense circulation of goods and people in the Iron Age, from roughly about 1000 BCE onwards. People now established permanent and culturally distinct settlements in ever more distant regions. This first led to pressures always coming with increasing diversity (Fuentes 2020) but ultimately to the emergence of break-through novelties like writing, urbanism and imperialism (Hodos 2020).

Through cross-cultural comparison imagination became both more diverse and robust. Around the middle of the first millennium BCE, a decisive breakthrough in Self-Other relations materializes in the Persian (Achaemenid) Empire. This is the first political entity in world history claiming that it is universal. Comparative history projects, like those by Herodotus, are part of this emergence of a global consciousness (Versluys 2022b). The appearance of the (radical) idea of cosmopolitanism around 500 BCE is a defining moment in the deep history of the Possible. People could now, for the first time in world history as far as we can tell, imagine themselves as belonging to an *oikoumenê*, the inhabited world pictured as a unified whole and in terms of some sort of transcultural equality. This made many (new) things possible and would ultimately result in the Universal Declaration of Human Rights (so Stuurman 2017). During the Hellenistic and Roman periods connectivity all across Afro-Eurasia is yet further increased which, in terms of imagination, leads toward something of a global cultural horizon in the period around 200 BCE (Versluys 2022b). More (intense) Globalization results in more (intense) Self-Other dynamics which give rise to more (intense) possibilities residing in all these encounters: this is how imagination is the motor of human development. In fact, this might be the real reason for the success of the emerging Roman Empire (or “la raison de Rome,” after Moatti 1997) or the emergence of the Han Empire in China: at the core of both was the (chronological and/or geographical) Other as action-orientation (Versluys 2022b). Objects continue to play an important role with that process (Pitts and Versluys 2021). As a result, Romans from the Republic and Empire are able to imagine a Greek past for their own culture while it was even possible for a Roman emperor to picture himself as an Egyptian pharaoh (Versluys 2017). In terms of Self-Other dynamics, this stretches the Possible to the extreme.

Conclusion

We conclude that the cosmopolitan imagination from Antiquity, to the extent that it was there, is a

situated process of the Globalization of peoples and things. This is not how we usually see our (“Classical”) past, but this relationship with the Possible may have been part of a conscious vision of the present and future of people from the ancient world. Some scholars now argue that it might even play a role for our own future (see Delanty 2006 on the cosmological imagination; as well as Latour 2021 when calling for a new form of universalism).

Keywords

Apperception · Einfühlung · Anticipation · Self

Apperception is central for the dynamics of moving on from sensory experience to thinking. As his cornerstone in educational psychology, Johann

Friedrich Herbart (1746–1831) formed the theory of apperception, with the function of presentations (*Vorstellungen*) as central for the understanding of the function of thoughts and the human mind. It is a concept that was crucial in philosophy and psychology, but since the 1930s its theoretical use has curiously vanished from psychology.¹

In most general terms, apperception was defined at its widest use times late nineteenth century as “*the process by which a mental system appropriates a new element, or otherwise receives a fresh determination*” (Stout 1896, p. 112). The focus on the notions of *system*, *appropriation*, and *fresh determination* is crucial here. The systemic look at the mental processes (which we nowadays call cognitive functions) was a crucial need for psychology at the time where the human psyche was found to be consisting of a very large number of mental elements. These elements joined together into particular structures, the systemic function of which was the main target for psychology’s target of investigation. The reduction of this focus to behavior and its modification by learning eliminated the structural systemic focus for a century. Secondly, the centrality of bringing in material from the environment and linking it with the previous structures antedates the focus on open systems that Ludwig von Bertalanffy introduced in the twentieth century. The bonding of new material to existing structures was central in Jean Piaget’s assimilation-

accommodation theory and found its place also in the various versions of sociocultural appropriation theories that emerged by the end of the twentieth century. Finally, the reference to fresh determination indicates alertness to the synthesis of novelty by the functioning psychological system that brings the nineteenth-century apperception perspectives close to twentieth century’s developmental science.

In personal phenomenology – the way in which we take in whatever we meet in our surroundings and in feelings and thoughts is crucial for the way we can interact with and feel into the world. It is not surprising that this focus emerged as relevant in the first centuries of emerging psychology (Klempe 2020).

Historical Overview

The notion of *apperception* comes from the work of Rene Descartes (1596–1650)² and Gottfried Wilhelm Leibniz (1646–1716) before Herbart and was further developed by Theodor Lipps (1851–1914), Wilhelm Wundt (1832–1920), and others (Jahoda 2006; Stout 1889a, b, 1891, 1896) who followed the contributions by Herbart. Probably the most recent effort to bring it to the scientific practices is that of the Thematic *Apperception* Test developed in the 1930s by Henry Murray and Christina Morgan.

Apperception in Philosophy

After Descartes, elaboration of apperception occurred in Leibniz’s *Nouveaux Essais – Principes de la nature fondés en raison et de la grâce* (1690/1981), where in chapter 9 he introduced it as the way to denote *being aware* – the faculty of the soul to deal with ideas by way of reflecting on the perceptual processes (Pape 1997, p. 1). The notion was relevant to focus on how an object that is foreign (“not self”) enters into relation with the

¹ As an effort to find out its status we looked into psychology curricula in Denmark. For example, the term “apperception” does not appear within the curriculum of the psychology study at Aalborg University, neither as part of the bachelor’s or master’s degree. A curriculum encompassing cognitive psychology, developmental psychology, social psychology, personality psychology, and psychiatry among others (Berk 2013; Ewen 2014; Fraser and Burchell 2001; Hogg and Vaughan 2008; Inglis 2012; Karpatschhof and Katzenelson 2002; Matlin 2009; Simonsen and Møhl 2017). We do not believe that this is a lack solely present at the local university. It seems it is a tendency across the scholarly field of psychology in general, where this notion which for roughly 100 years ago with good reason was very discussed but over past decades has not been present. Partly that can be due to the unfocusing by psychology on sensations as elements of experience and working at the more integrative level of perception instead.

² As he used the word *apercevoir* in his book *Traité des passions*.

self. It was developed in opposition to John Locke's British empiricist beloved locus on *tabula rasa* and the associationistic buildups on that (Capesius 1894). Apperception is distinctively a Continental European concept. Immanuel Kant differentiated transcendental and empirical forms of apperception. The first entails "pure" unchangeable consciousness that is the basis for all experience. The latter the ways in which the actual self changes itself.

Johann Friedrich Herbart as the Key Author in Understanding Apperception

It is in the beginning of the nineteenth century that the notion of apperception found its focus of attention in the emerging psychology. Johann Friedrich Herbart played a central role in this emerging psychology – being the initiator of social psychology (Jahoda 2006) as well as introducing the first university lecture course in 1806 in Göttingen. His role in mathematization of psychology has been well known in history of psychology.

The key starting point for Herbart's look at apperception is his focus on presentational mass (*Vorstellungsmass*) that becomes organized by the apperception system. In terms of George Stout,

Apperception is the process by which a presentation-mass assimilates relatively unstable groups, fusing with homogeneous, and repressing antagonistic, elements. The new material assimilated may be either given in sensation, or reproduced by the internal working of the psychological mechanism. In the former case the process is called outer apperception; in the latter it is called inner apperception. (Stout 1888, p. 484)

This role of selection between sensations – inner or outer – attributed to apperception situates the concept as closely linked with the whole field of human sensations – the elementary units of the psyche as these were investigated in the nineteenth century. Once the focus moved away from the study of sensations into that of perception and action in the twentieth century – and away from synthesis focus – the notion of apperception lost its place.

The contrast between inner and outer apperception was important for Herbart:

In outer apperception the sense-affection is produced before it is apperceived. At the outset it possesses more unarrested intensity than is compatible with the conditions of equilibrium. Hence it has an initial advantage in the conflict with pre-existing contrary presentations, so that it causes them to sink towards the mechanical threshold, or even below it. At the same time, by immediate reproduction, it recalls or raises to fuller distinctness presentations which resemble it. These emerge slowly at first, but with gradually increasing rapidity. (Stout 1889b, p 366, added emphases)

The primacy of affect in outer apperception fits the needs for adaptation to incoming challenges – flexibility in relating to the stimulus. This is the location where innovation to the reaction – based on the form of the apperception – is being established.

Herbart's perspective on apperception was elaborated in chapter 5 of his classic *Psychology as Science* (Herbart 1825). As we can see from Fig. 1, Herbart saw the notion of apperception relevant in all four domains of the psyche: experiencing, acting, wanting, and willing. All these domains are coordinated by the personal come – *Das Ich*. It provided an interesting epistemological problem for Herbart.

Looking for the Center: The "I" Cannot Be Found

Ich ("I") is the hypothetical and no more reachable starting point for the apperceptive processes. In Herbart's own words,

The I is a point which is and can only be presented in so far as innumerable rows point back to it, as their common law in advance.³

This can be to be the bridge between transcendental (not reachable) and empirical sides of the apperception (following Kant). The initial point (I) is assumed in backward projection of various

³In the original "*Das Ich ist ein Punkt, der nur in so fern vorgestellt wird und werden kann, als unzählige Reihen auf ihn, als ihr gemeinsames Vorausgesetz, zurückweisen*" (Herbart 1825, p. 251).

Apperception, Fig. 1 Herbart's categories of inner apperception (Herbart 1825, p. 251)

trajectories known empirically in the present as moving to the future and can be extrapolated to the past (Fig. 2), yet can never be directly proven. The unreachability of the past I point is proven by irreversible time – which was not emphasized in European philosophy until 1890s when Henri Bergson made it into the central parameter of his philosophy.

Theodor Lipps: Apperception and *Einfühlung*

Theodor Lipps would have been the main thinker of phenomenology in the twentieth century had not the shadow of Edmund Husserl captured the field. His systematic analysis of aesthetics (Lipps 1903) and architecture (Valsiner 2018) would provide a missing link to contemporary psychology

that has overemphasized language and narration over silence and basic aesthetic forms that have longevity over centuries.

In his book *Vom Fühlen, Wollen und Denken* Lipps (1902) unified the notion of *Einfühlung*⁴ with apperception and the *Gegenstandstheorie*⁵ of his time. The crucial specific issue is the perception of the nonperceivable beyond its control

⁴Which is the process of feeling-in an object, and through that feeling – feeling further forward within the self. I look at flowers in a vase and feel “this is so beautiful” – and by such relating I guide forward my aesthetic feeling into the rest of the world, creating beauty on next occasions looking at flowers. A bee collecting nectar from the same flowers would not develop the feeling of beauty.

⁵Developed in late nineteenth century by the Graz School of Alexius Meinong. The basic notion of a *Gegenstand* entails a directional vector oriented toward some border that is maintained by a counter-vector: $\rightarrow \parallel \leftarrow$.

Apperception,

Fig. 2 Back projection of trajectories of apperception to locate the “I”

ends. The person looks at the sea horizon and imagines what might be beyond that horizon. Of course the imagination is dependent on what *is* perceivable – and unified by the act of apperception. It is the general apperceptive feeling-in (*allgemeine apperzeptive Einfühlung* – Lipps 1903, p. 241) that leads the person to attempt to move beyond the marked ending of the object. Feeling into the environment is based on the apperception of the possible continuity of the form beyond the perceivable.

Wilhelm Wundt: The Subjective-Objective Contrast

Similar example of the centrality of the process of apperception is brought forward by William Wundt as our understanding of words is going through the process of apperception to become meaningful constructs rather than mere sounds, and that we use such function constantly in our verbal lives (Wundt 1912).

The issue of apperception was crucial for Wundt from the very beginning of his work (Wundt 1862) to the very ripe period of his work at the end of his life (Wundt 1912). In continuity with the ideas of Herbart and the Herbartian disciples of early *Völkerpsychologie* (Moritz Lazarus and Chaim Steinthal – Volkelt 1924), Wundt

borrowed the notion of multiple flow of presentations (*Vorstellungen*) that are built on the experience of the total flow of the elementary units of the psyche – sensations. The experience of sensations goes through the passive>active and subjective>objective sieve – where the rational (cognitive) and subjective (affective) contrast was exemplified by the latter. The feelings that are triggered by sensations – some becoming extinct together with the sensation while others retaining the affective impact of sensations over time (“feeling tone” – Hollands 1906, p. 208). Within this domain of lingering feeling tones the apperceptive processes establish their further mastery of turning the feelings into ideas, images, words, and – eventually – generalized concepts (Wundt 1893, p. 37 on *apperceptive synthesis*) as well as feeding into volition. The notion of abstractive synthesis in the human mind is made possible by the mechanisms of Gestalt building by apperception. That process is also the link between the elementaristic experimental psychology of Wundt’s laboratory in Leipzig where the investigation of self-perception (*Selbstwahrnehmung*) was strictly separated from the study of higher psychological functions that Wundt’s *Völkerpsychologie* in the first two decades of the twentieth century depicted. In both – elementaristic and higher mental functions analyses – the synthesis was to occur from

elements upward toward structured complexes (of perception or myth). Gestalts were assembled from elements – and apperception with its starting point in the affective flow was the means to that end.

New Look at Apperception: Anticipating the Future as Arriving in the Present

The focus on apperception has been disregarded within modern psychology. But apperception as a function of the individual's perceiving in irreversible time accounting for the role of imagination within the human psyche is a central part of the way human beings experience in everyday life inseparably with social constructs.

Our everyday lives give us ample evidence about the central role of apperception. A relevant example of how action of apperception is present in moments of ordinary uncertainty can be taken from living in a time of the COVID-19 pandemic.

As X is standing in line in the narrow aisle of the grocery store a stranger walk down this narrow aisle against the flow of everyone in line and the arrows on the ground. The stranger is not coughing or in other was showing visible signs of being ill, but X feels scared of being infected with the coronavirus by the stranger.

In the example X does not know whether the stranger is a carrier of the coronavirus or not, and the feeling of fear does not emerge solely as X perceives that a stranger is walking past. The fear emerges due to apperception, which is linked with the function of imagination. The imaginary understanding of the stranger as having the coronavirus which *of course* will be transferred to X by the stranger passing, maybe the stranger will cough that instant or simply by the look. Because of this imaginary idea of the stranger X now apperceives the stranger as a danger. It is therefore not from merely perception of the surroundings that creates X's experience in that present moment, it is the social construction and imagination of X's which affect how X is feeling. X is not afraid of the stranger standing behind in line, mind you if this person is not overstepping the marked "safety-box" on the floor, but that

another stranger is going against the (new) social norms can lead to an emergence of a feeling of great turmoil.⁶ The internal reality of X's is not simply the mere perception of what is in the world at the given moment in time, but it is an understanding that is connected with the irreversibility of time, as the imagination which is future oriented influences the current moment, which is the act of apperception. This is as well illustrated by the mental activity of the chess players,

A chess-player need not in actual play think about the general laws of the game or about general maxims derived from previous experience. It is much nearer the truth to say that he thinks by means of such laws or maxims than that he thinks about them. His insight into the dangers and advantages of a particular position, the particular move which suggests itself to him at any moment, his prevision of the line of play which is likely to be adopted by his adversary, are all due to the operation of an apperceptive system which has become organised in the course of previous experience. This system is the unity in which are combined the blended products of many particular experiences. It is therefore a universal. But its universality is exhibited only in the general plan of synthesis by which particular objects of attention are interconnected so as to form an intuitional whole. (Stout 1891, p. 193)

What becomes central in the use of apperception is its role in educating the *generalized intuition* – feeling into the knowledge domain (be it chess or any other domain of experience) so that the person preemptively can make decisions in ways that are not clearly calculated. They cannot be – since the irreversible time proves the adequacy of Herbert Simon's view of *satisficing* being adequate in settings where conditions are constantly changing. *Optimizing* – the favorite mantra of economists and administrators – is simply not possible in the human mind. Figure 3 illustrates a new location for apperception in the future-oriented thinking schemes.

⁶We do wish to note that we certainly respect the health concerns of the current situation we are in, as well as respect others' precautions due to diverse physical and mental health issues. Here we simply wish to show how the phenomenon of apperception is rippling through our everyday lives.

Apperception, Fig. 3 New model of apperception in the context of irreversible time

Figure 3 illustrates apperception as a process in the span of irreversible time. A process which exist within the present moment, as any function in life, intertwined with the reconstructed memory of the blur of the past. The blur of the past resembles a hotchpotch of past experiences, which never can be experienced exactly as they were experienced and often will be affected by other past experiences. And furthermore, intertwined with the imagination of the possible future. All a collected process affecting the way in which the individual understands the experiences inside and outside of the self.

The Basis for Apperception: Anticipation

Anticipation – expectation of something that might happen – characterizes all forms of life. In the flow of ongoing living any adaptive action only is possible on the basis of anticipation (Toomela 2015), and it is relevant to study within a wide variety of perspectives ranging from neuroscience to philosophy, economics, and psychology to name a few. The extent to which it has been studied is only a small field of contemporary research. Therefor the scholarly insight into the phenomenon of anticipation is limited. The research on the phenomenon of anticipation is mostly based on cognitive and neuroscience and

grows out of work from over the entire past century, and recently has the insight from classic scholars in physiology and organization of goals-directed movements (Bernstein 1940) who were the essential pioneers within the field of study of anticipatory processes (Nadin 2015; Poli 2017).

The notion of anticipation is used in different ways, as a lay term it refers to future-oriented experiences and set in line with forecasting, predication, expectation, and prospection, which scholarly has been pronounced insufficient in that the phenomenon of anticipation exceeds any reduction to psychology, physiology, or any other field, as it ranges over a wide spectrum (Nadin 2015). Within the scholarly field of studying anticipation there exist divergence in regard to definition of the phenomenon of anticipation, and many central elements such as how it occurs and which types of anticipation can be distinguished still hold uncertainty (Nadin 2015; Poli 2017). Studies have however shown how diverse forms of anticipation exist and how it is relevant to distinguish biotic and psychic forms of anticipation (Toomela 2015). As in other domains the difference between biotic and psychic forms are on fundamental levels diverse. To set it up rather harshly is biotic anticipation for the sake of the species (with slowly

emerging novel forms of anticipation for adaptation for the survival of the species not necessarily the individual) and psychic anticipation is for the individual's well-being and function in life (highly linked with the individual's sense-making processes and ability to function, which also consist of learning how to predict the future) (Toomela 2015). Studies of anticipation are mainly from cognitive and neuroscience perspectives, which is not transmittable and sufficient for comprehending subjective experiences of psychic anticipation (as could emerge in silent experiences), which always will remain new for every emergence. As mentioned above did Lehmann et al. (2018) show a connection between experiences of surprising silences and feelings of anticipation as a tension between expectations and reality.

Interestingly anticipation is linked with events that are about to happen. It is not present within a state of silence. In that state anticipation vanishes – even if for very short moments. These as the phenomena of silences and silence are, though at times linkable, two completely diverse phenomena (Røgild-Müller 2020). The phenomenon of silence is that of complete presence – experiencing the silence in its fullness.

Summary: Bringing a Forgotten Concept Forward to New Life

What is the value of history in psychology? Very often we hear dismissive voices about history of a science – it is a storehouse of failed ideas that have proven wrong in the constant progress of science. Nothing can be more far from reality where different ideas about the subject matter in a given discipline go through nonlinear developmental trajectories. For long times these ideas may be ignored, at times discovered as if a completely new and fashionable way of thinking (e.g., cognitive science being built on the mental psychology of early twentieth century but not recognizing that continuity) – only to give way to another fashion. Fashions do not create new knowledge but merely redress the previous realm of our understanding.

Our effort in this entry was precisely the opposite – to bring back a particular lost concept and situate it in our current science of cultural psychology. What we have done in this small overview of an old but forgotten concept is to bring it from the oblivion of collective forgetting to a new life. The new focus – especially in cultural psychology of semiotic mediation – on the centrality of irreversible time in human psychological functions gives apperception a renewed relevance in the relating with the environment. In every psychological process oriented toward the immediate future there is uncertainty about that future necessarily involved. That uncertainty is overcome by structuring the anticipatory act to face the possible future – by structure of apperceptive kind. It is here where the affective primacy of the human adapting mind is located.

A very fitting example of where the notion of apperception is necessarily in the center of the specific cognitive functions is Gerd Gigerenzer's theory of fast and frugal heuristics. Gigerenzer (summary in Gigerenzer et al. 1999) proved that in the actual decision making in ordinary circumstances the time pressures do not allow the decision maker to calculate all the versions of possible actions and their costs and benefits, not to gather full information about all the context. The decisions are made on intuitive basis – quickly (fast) and robustly (frugal) – and turn out to be sufficiently adequate. Yet the mechanisms of such rapidly functioning processes needed further clarification. Gigerenzer imported evolutionary psychology to support the adaptability of such fast and frugal mechanisms. While reference to evolutionary pressures may explain the need for emergence of such rapid cognitive tools, how the fast and frugal process works remains a mystery. No classical experimental design – oriented to the outcomes of the heuristic use – can explain the ways in which the rapid processes proceed. Apperception is a likely candidate to explaining this. This can be observed in the historical background of the heuristics idea that goes back to the work of Otto Selz in the beginning of the twentieth century and its role in looking on decision processes beyond the notion of logical computations (Wettersten 2017). The general aboutness of

the heuristics is the arena for apperception to work toward synthesis of decisions.

Scientific concepts are like musical instruments – needed in coordinated fashion to play various pieces of music. Psychology has had very little stamina in teaching its theoretical concepts how to relate to one another to arrive a full understanding of the depth of the psychological phenomena. Instead, psychological theories operate like street musicians collecting alms for the limited coverage of the whole complexity of human lives as dramatic operas.

Archetypes

Webster University, Geneva, Switzerland

Abstract

The notion of archetype, although already present in Western culture since ancient Greece, is associated to the name of the Swiss psychiatrist Carl Gustav Jung (1875–1961), who gave the concept both a universal and a psychodynamic connotation. Universal, because archetypes are the contents of the collective unconscious, which is the common unconscious substratum that connects every human. Psychodynamic, since archetypes are patterns of behavior, i.e., they regulate human behavior according to inborn schemata similar to instincts. Jung formalized the double nature of the archetype in 1946 and differentiated between archetype as such and archetypal image, the former being a “psychoid” factor inaccessible to consciousness while the latter can reach consciousness in the form of universal symbols.

This distinction makes the archetype an agent of inner and outer change that links together biology, psychology, and culture. When consciousness is torn between opposites, an archetypal image emerges to bridge the split, thus promoting a new conscious attitude. In the role of union of opposites from which a third is born, the archetype becomes a holder of potential and a catalyst of creativity on both a personal and a collective level.

This entry defines the notion of archetype, outlines its history, and presents the Jungian model of the psyche, including the dynamic notion of the unconscious from which stems the potential of the archetype.

Keywords

Archetype · C.G. Jung · Collective unconscious · Complexes · Creativity · Individuation process · Inspiration · Shadow · Synchronicity · Transcendent function

Definition and Brief History of the Term

The notion of archetype has been in Western culture since ancient Greece, where the term *archetypos* conveyed the idea of an original form, a very first pattern. At its core, the word *arche*, which meant *principle* or *origin*, was used in Greek philosophy to indicate the primordial substance and, with Aristotle, the principle of knowledge. *Typos*, the other component of the word, meant *form* or *type* and carried the idea of an imprinting. Through its Latin translation *Archetypum*, the word was acquired to the Western languages in the meaning of original model or prototype. In this definition, the archetype can be conceived as an original form that organizes a variety of contents within the same structure, very much like the platonic forms.

The term remained confined to scholarly domains such as philosophy and theology until the beginning of the twentieth century, when the Swiss psychiatrist Carl Gustav Jung introduced it in the field of psychology for the first time in 1919 (Jacobi 1999). Jung named “*archetypes* of perception and apprehension” the “*a priori* inborn forms” of the collective unconscious, “which are the necessary *a priori* determinants of all psychic processes” (Jung 1919, CW8, para 270). In this definition, archetypes are the universal structures or patterns of behavior that regulate psychic processes on both an individual and a collective level.

Although borrowing the term from St. Augustine, Jung was inspired by the *Corpus Hermeticum*, which describes God as the archetypal light, i.e., “the prototype of all light” (Jung 1919, CW8; Jung 1938, CW9, I, para. 149). Along with the notion of prototype, which was influenced by the platonic theory of forms, medieval philosophy introduced the connection between the *a priori* forms and the human mind. More particularly, in Scholasticism “we find the notion that archetypes are natural images engraved on the human mind, helping it to form its judgments” (Jung 1919, CW8, para. 275).

This connection, which in Jung’s understanding is particularly relevant for psychology, was lost after the Scientific Revolution. The notion of archetype, then, gradually lost its metaphysical

connotation to become a mere “thought” in Spinoza, and a category of understanding in Kant (Jung 1919, CW8).

Once acquired to analytical psychology the term archetype became more commonly used while the Jungian theory gradually expanded to other fields, including art and literature, and, in recent times, organizational psychology and marketing.

C.G. Jung and the Archetypes

The elaboration of the theory of archetypes was for Jung a long endeavor that lasted over 30 years, from the first hypothesis in 1912 to the final theory in 1946. The reason was the complexity of the topic together with the difficulty to translate into theory his empirical observations, as psychology was a new science that lacked universal truths. Moreover, Jung’s circular and encyclopedic method of work required a lot of time: Jung would elaborate an initial concept, then amplify it through further readings in many fields other than psychiatry, and finally go back to the initial notion to perfect it (Shamdasani 2003).

In the Jungian model of the psyche archetypes are closely related to the collective unconscious, which is the deeper and universal layer of the unconscious common to all individuals. In contrast to the personal unconscious, the collective unconscious “does not derive from personal experience and is not a personal acquisition but is inborn”; it is “identical in all men and thus constitutes a common psychic substrate of a supra-personal nature which is present in every one of us.” Because the unconscious is alien to the conscious, we can only apprehend the unconscious through its contents that can emerge to consciousness. The contents of the collective unconscious are the archetypes while the feeling-toned complexes are the contents of the personal unconscious (Jung 1954a, CW9,1, para 3,4).

Jung laid the cornerstones of his theory as early as 1912 when he published *Wandlungen und Symbole der Libido*, the book that marked the split with Freud and that, in its later and revised English translation, was called *Symbols of*

Transformation (CW5). In the book, Jung frees the notion of libido from the Freudian identification with the sexual drive and gives it the broader sense of psychic energy, emphasizing the dynamic, symbolic, and transformative character of the libido in the human psyche. In Jung’s view, human beings are connected to the many historical and cultural layers made by their ancestors through “fantasy thinking,” i.e., the sort of thinking that shapes the symbolic language of dreams and myths (Jung 1912, CW5). He used the expression “primordial images” to indicate all the collective images and themes from myths, legends, and fairy tales that tend to form recurrent patterns throughout the world from immemorial time. The collective and inherited nature of the primordial images explains the fact that the same symbols found in legends and fairytales are also found in dreams and in the delusions of psychotic patients (Jacobi 1999; Jung 1917, CW7, para. 100–101).

The theoretical developments that Jung published in 1912 were the result of several years of research and practice at the Burghölzli, the psychiatric university hospital in Zurich where Jung worked from 1900 to 1909 under Bleuler’s supervision. The observations of schizophrenics and their delusions contributed to the idea of a deeper, objective, and collective layer of the unconscious whose contents were symbolic images recurrent in many different cultures throughout the world.

In this regard, Jung mentions an episode that occurred in 1906. He came across a vision in a paranoid schizophrenic that had as a central image the penis of the sun which was generating the wind. Four years later, Jung read about a Mithraic ritual that presented a similar theme of a wind tube connected to the sun god. Knowing that the patient, who was a simple man and had been interned for many years, had no awareness of the existence of the Mithraic myth, Jung came to the conclusion that both the theme of the delusion and the one of the Mithraic ritual were “representations collectives” (Jung 1936, CW9.I, para. 105–106). Similar representations seemed to surface from dream analysis and active imagination, a technique created by Jung to reproduce a dream-like state in which unconscious contents emerge

to consciousness. All these findings seemed to point to the existence of universal and highly symbolic themes or images, such as, for example, the opposition between light and dark, the union of the opposites in a third, and abstract geometrical figures.

As for the archetypes, Jung first called them *primordial images*, then *dominants* of the collective unconscious, and finally in 1919 he introduced the term *archetype* to signify a mode of apprehension correlated to the instinct (*Instinkt*). While the instinct produces the immediate behavior, the archetype offers the intelligible image behind the behavior (Jung 1917, CW7; Jacobi 1999; Jung 1919, CW8).

The connection between archetypes and instincts is an attempt to clarify the dual nature of the archetype, which is both instinct and image, spirit and matter. The composition of the paradox arrives in 1946 when Jung differentiates between archetype as such and archetypal image. The former is a “psychoid factor,” *i.e.*, inaccessible to human consciousness, while the latter is an archetypal representation that is able to become conscious. Imagining the existence of a threshold under which the unconscious contents cannot reach consciousness, the archetype as such is below that threshold: Although organizing human behavior, it stays transcendent and can become conscious only through the archetypal image.

Archetypal images are highly symbolic and carry a strong power of attraction and transformation. During psychotherapy, the conscious integration of symbols from dreams, synchronicity, and active imagination brings a process of behavioral and psychological change that Jung called the individuation process, *i.e.*, the process of truly becoming oneself. In this way symbols, with their multilayered and captivating meaning, become the carriers of the transforming power that archetypes exert on the human psyche.

Symbolic Dynamics and Characteristics of the Archetypes

The compelling power of the archetype on the individual stems from its being a numinous factor

with a “*feeling-value*.” Numinosity, which is the quality of the divinity and the supernatural as experienced by humans, gives “*dynamism*” to the archetype and fascinating power to the archetypal image. Similar to an instinct, the archetype can be paradoxically experienced as “physiological dynamism” that comes to consciousness as “images or group of images,” which carry a strong feeling tone and have a numinous effect. These images exert a power of attraction and, through their integration to consciousness, induce change (Jung 1954b, CW8, para. 414).

The transformative power of the symbol is made possible by the fact that “psyche and matter are two different aspects of one and the same thing.” Due to its psychoid and symbolic nature, the archetype presents itself as a bridge between two worlds, the world of spirit and the world of matter; however, because both spirit and matter need to be mediated by the psyche in order to access human consciousness, Jung mainly talks of the archetypes in terms of psychic phenomena (Jung 1954b, CW8, para. 418).

The connection between psyche and matter can be seen in the phenomenon of synchronicity, which is a meaningful coincidence where a physical event seems to happen in correspondence to a psychic one, and mirror it. The two events are not regulated by causality but, rather, by “a falling together in time, a kind of simultaneity” (Jung 1952, CW8, para. 840).

An example of this correspondence is an episode that occurred to Jung during a session with a young woman. While she was describing an image from a dream of hers where she was given a golden scarab, in that very moment a scarab-like insect, a *Cetonia aurata*, knocked at the window pane, then entered the consulting room. The power and the meaningfulness of the experience is expressed in Jung’s comment: “I must admit that nothing like it ever happened to me before or since, and that the dream of the patient has remained unique in my experience” (Jung 1952, CW 8, para. 843).

This case points to the archetypal basis of synchronicity: the scarab as a symbol of rebirth and transformation came in a moment where the patient felt stuck and in need of a deep change.

The archetype, first constellated in the dream and then mirrored by the synchronistic event, appears to compensate for the one-sided rational attitude of the dreamer and provokes an essential change, *i.e.*, psychic renewal or rebirth. The numinosity and the feelings of awe elicited by the episode, which made a strong impact on both the patient and the therapist, confirm its archetypal nature, since the numinous effects of the archetype “express themselves as *affects*” (Jung 1952, CW8, para. 841).

Synchronicity is a good example of how the archetype organizes unconscious psychic processes: the archetypal image, which in synchronistic episodes is doubled by a correspondent objective event, catches consciousness, “sets it in motion,” and becomes conscious, thus organizing human behavior in a meaningful way correspondent to the symbol.

Contrary to the archetype as such, which Jung describes as *coincidentia oppositorum*, the archetypal image reaches consciousness in a multiplicity of facets organized around a positive and a negative pole. As an example, the Mother archetype, in its symbolic representation, includes a broad range of meanings that go from the nourishing aspects of the positive mother to the devouring sides of the negative one. In its positive aspects, the mother archetype is a vessel, a spiritual container, a shelter, and a life giver. It is abundant, accepting and all-nourishing, as symbolized in the breast and breastfeeding motif, and in figures such as Demeter, the virgin Mary, and the ancient goddesses of fertility. In its negative character the mother archetype becomes the “devouring womb of grave and death,” the Queen of the underworld who brings destruction, as symbolized in the goddess Kali and in monsters such as the Gorgons (Neumann 1983, p. 149). This same duality can be observed in real life where mothers can be both givers of life and perpetrators of infanticides, nourishing and destructive. The two poles can also cohabit in the same individual, man or woman, who can hold a nurturing attitude or a devouring one, depending on life situations.

Opposite to the duality of the archetypal images stays the centering effect of the archetype

through the symbol: When the ego is torn between opposites, the emergence of a symbol bridges them and creates a third way, which makes the symbol a mediator between conscious and unconscious.

Psychic processes are in their essence a phenomenon of energy that, like other forms of energy, proceeds from the tension of opposites. This is why the law of *enantiodromia*, for which “sooner or later everything runs into its opposite,” is for Jung “the most marvellous of all psychological laws” (Jung 1917, CW7, para. 34 and 111).

In other words, the psychic dynamic is an interplay of opposites striving for balance. When the psychic energy becomes one sided, a symbol appears to compensate the conscious attitude, thus allowing the libido, previously blocked into the unconscious, to flow again. An example of this dynamic is the case of synchronicity discussed above, where the scarab, as a symbol of transformation and rebirth, comes to compensate a conscious rigid attitude and the feeling of being stuck.

The potential of the archetype resides in the emergence of the symbol from the dynamic of the opposites, *i.e.*, the dynamic between conscious and unconscious whose divergent contents establish a relationship of reciprocal compensation. The symbol creates a dialogue between the two, as “both are aspects of life.” Psychic life can only unfold through the constant dialogue and open collaboration between conscious and unconscious, from which emerge new conscious attitudes. During the process of psychoanalysis, the repeated appearance of the transcendent function, *i.e.*, the bridging of the opposites through the symbol, enhances the individuation process, which is the “rounding out of the personality into a whole,” in a creative dynamic that establishes a contact with the centering principle of the whole personality and actualizes the individual potential (Jung 1939, CW 9,I, para. 522 and 224).

The Potential

We call the unconscious ‘nothing,’ and yet it is a reality *in potential*. The thought we shall think, the deed we shall do, even the fate we shall lament

tomorrow, all lie unconscious in our today. The unknown in us which the affect uncovers was always there and sooner or later would have presented itself to consciousness. (Jung 1939, CW 9,1, para. 498)

In the Jungian model of the psyche the potential stems, first and foremost, from the idea that the unconscious is not a mere container of repressed elements, but rather a vast, dynamic, and powerful force of nature that encompasses past, present, and future, and regulates, shapes, and even disrupts human life. Jungian psychotherapy has at its core the dialectic between conscious and unconscious, which continuously creates new synthesis and is a harbinger of future developments. However, the interaction between conscious and unconscious can result in both psychic conflict and growth. The conflict occurs whenever the conscious mind attempts to dominate or suppress the unconscious contents while psychic growth happens when the conscious establishes a dialogue with the unconscious.

In their quality of unconscious contents that can reach consciousness, the archetypes are the principal actors of the dialogue between conscious and unconscious where they guide the conscious attitude toward change and renewal. Patterns of behavior, they are life in a nutshell since they structure the reality that will unfold, and shape the meaningful moments in human existence.

For their closeness to instincts archetypes have a tangible impact in shaping human behavior throughout life. In our first years, we are guided by the *puer archetype*, while the *senex* accompanies our last years. The activation of the *syzygy* or conjunction leads us toward marriage while the mother and the father archetypes guide motherhood and fatherhood. Moreover, each archetype elicits its opposite, thus giving, for example, glimpses of wisdom to the child, and playfulness to the old wise man.

During therapy, the appearance of an archetype announces a creative process, which channels the paradoxical nature of the psyche toward the emergence of a third. As union of opposites, the archetypal image offers to consciousness the unknown side, which starts a process of transformation and

creation of new perspectives. Jung calls transcendent function the progressive development toward a new attitude, which “arises from the union of conscious and unconscious contents” and brings a sense of wholeness and reconciliation (Jung 1957, CW8, para. 131).

The transcendent function bridges the opposition between conscious and unconscious, and offers the opportunity of a new synthesis. Once the opposition is transcended, a new antithesis will appear in search for equilibrium. The synthesis will come again, in a nonlinear and metaphorical way through a new symbol. This ongoing process of psychic transformation is the expression of the purposefulness of the unconscious that guides us toward the goal of becoming who we really are. More than a static and permanent acquisition, the goal indicates a horizon while the path toward the horizon is the individuation process, which implies a broadening of consciousness through the confrontation with the unconscious, and a synthesis of the opposites through the emergence of the symbol.

The process of creating oneself, which proceeds from inner division toward inner wholeness, unfolds through the encounter with a number of archetypes, which appear in dreams and synchronistic events, and the integration of the feelings attached to them. Although the archetypal images vary according to the individual path, some of them are particularly meaningful, as they are consistently present during the individuation process. These are the *shadow* and the *persona*, the *wise old man*, the *child*, the *mother* and the *maiden*, the *anima* and the *animus*, and finally the *self*, which is the center of the whole personality, conscious and unconscious. The symbols of the self often represent the potential, such as the egg and the divine child, and the indestructible, such as the diamond and the stone; they can also show in abstract and geometrical shapes, such as the mandala (Jacobi 1999, p. 114).

The archetype of the self contains the potential for both centeredness and self-actualization. The mandala and the fourfold symbols refer to the stable, eternal, and structured nature of the psyche in its state of pure being; on the other

hand, the symbols of threefoldness represent the developmental process of becoming oneself. The self is, therefore, both being and becoming, in a combination that results paradoxical to human consciousness (Edinger 1972).

From the paradoxical nature of the archetypes stems the potential for change and creativity. In the individuation process, the turning into the opposite can be understood as an alternance of growth and contraction where negative symbols turn into positive one. As an example, a negative father complex will show in dreams as negative male figures that, once integrated to consciousness, will transform into positive father figures, thus modifying the actual negative experience of the father into a broader conscious perception that includes the positive aspects as well. However, the expansion enhanced by the broadening of consciousness could not happen without the sacrifice of old attitudes, which is the antidote to the inflation of the ego.

The alternance of growth and sacrifice, expansion and contraction, marks the rhythm of psychic life where to creation can follow destruction. In fact, the archetype's creativity can become destructiveness whenever the individual ego is incapable to differentiate between conscious and unconscious contents. In this case the ego identifies with the archetype thus losing contact with reality, as observed in schizophrenia. As a result, the negative pole of the archetype can become a haunting persecutor and display all its destructive power.

The destructiveness of the archetype can be experience on both an individual and a collective level. This is the case with the *shadow*, i.e., the dark side of personality that appears in dreams as the personification of unwanted aspects of ourselves. When unconscious, the shadow is easily projected onto others with negative feelings such as rejection and despise. On the other hand, the awareness of one's own shadow sides brings the sense of one's own imperfection and a feeling of humility. Moreover, the shadow presents the potential inherent to the rejected aspects of personality. As an example, for an extravert who despises introverts, the contact with the repressed

introversion will expand the range of personal expression and improve the relationship to oneself and to others.

On a collective level, the shadow is represented in figures of absolute evil, such as the devil, which can be projected onto an outgroup and result into conflict, violence, and even genocide. History offers many examples of this dynamic throughout the centuries and throughout the world, where a minority receives the projection of pure evil, thus becoming the object of moral exclusion and extermination. On the other side, the integration of the shadow on a collective level allows the inclusion to society of people and parts that appear to not conform to the mainstream, thus enriching the collective consciousness with new sides and possibilities.

Transforming one's own life is an act of creation, however not the only one. The potential of the archetypes also manifests in paintings, fairy tales, artifacts, novels, movies, and all those things and ideas that humans have created in different times and cultures of the world.

In his *Six Memos for the Next Millennium*, the Italian writer Italo Calvino supports the idea that the source of creativity is an unconscious image that appears to consciousness and inspires the creative work. Artists and writers do not know where the image comes from, as much of the source is unconscious (Calvino 1988). On the same line of thought was the physicist Wolfgang Pauli who was in analysis with Jung and collaborated with him on the concept of synchronicity. Pauli thought that creative ideas, including scientific theories, are born from the encounter between the outer reality and the archetypes (Pauli 1994).

Thus, in their role as organizers of human apprehension around a symbolic image, the archetypes can guide creative processes and regulate the communication between the individual creativity and the collective unconscious. Ancient Greeks symbolized the creative process in the nine Muses, to signify that inspiration comes from the beyond. However, Mnemosyne, goddess of memory and mother of the Muses, is a reminder that inspiration also has an historical color, since

every work of art carries the memory of what has preceded. As for the archetypes, they are a source of inspiration especially for their capacity to bridge matter with spirit, and history with the beyond.

To sum up, the potential of archetypes resides in their capacity to compensate and transform our conscious attitude, and to structure our life both on an individual and collective level. In times of change, the emergence of archetypal images puts us in contact with the other in us, thus bridging our inner conflicts with a creative solution, and helps us create new attitudes. Moreover, for their capacity to bridge spirit and matter and to access human consciousness through symbols, archetypes are the source of inspiration for artists, scientists, and other creators.

However, opposed to the constructive and creative cycle stays the destructive one that appears whenever the personal or collective ego identifies with the positive pole of the archetype, thus projecting the split negative part onto another individual or group.

Conclusion

Jung emphasized the fact that the psyche is composed of two halves, the conscious and the unconscious, that are opposite and difficult to harmonize. However, the relationship between these two halves is vital to our psychological well-being on both the individual and the collective level. In the encounter with the unconscious, and the opposition that goes with it, the archetypes have a crucial role to play in expanding human consciousness and in creating psychic life.

On the individual level, archetypes organize psychic growth through the individuation process and offer the experience of the unknown. Moreover, they structure the meaningful moments in human life and guide human beings through change. On a collective level, archetypes are the source of creativity and organize human apprehension, thus directly influencing collective trends. Similar to the collective unconscious of which is a part, the archetype is a force of nature, which can

be both constructive and destructive, depending on whether or not the conscious is capable to differentiate and open a dialogue with the unconscious.

The Jungian distinction between an instinctual and a symbolic part to the archetype has left room for debate. The definition of the archetype has a spectrum that goes from nature to culture where the connection between the two can give rise to different interpretations. In recent years, the debate on the nature of the archetype has proposed two main perspectives: on one side, the evolutionary model based on the identification between psyche and biology; on the other, a multidisciplinary model that, although not denying the importance of the biological element in the theory of the archetype, supports the differentiation between psychology and biology. Antony Stevens, a representative of the evolutionary model, considers archetypes as innate neuropsychic structures ingrained in the genetic structure, “which evolved by natural selection to accomplish certain specific goals.” Opposed to this view is George Hogenson who considers the archetypes as “the emergent properties of the dynamic developmental system of the brain, environment and narrative,” which have no location in the brain (Hogenson et al. 2003; Hogenson 2019).

Regardless of the perspective, the notion of archetype still dwells in the contemporary Western culture several decades after Jung’s death. Besides the world of analytical psychology, where the debate is still alive, the reference to archetypes permeates diverse areas of culture, which are not bond to psychology. These go from literature, where phantasy novels display characters that often embody archetypal images, to philosophy with Bachelard’s philosophy of imagination and his books on the four elements, and to marketing, where branding and advertising are built around an archetype in order to catch the customer’s interest through an unconscious and compelling message.

Although unorthodox, the use of archetypes in the field of marketing shows the extent to which Jung’s theory has influenced Western culture, way beyond the field of analytical psychology. In fact,

the success of the Jungian theory of archetypes can be ascribed precisely to its capacity to expand in other fields thanks to a model that encompasses biology, psychology, and culture.

Abstract

Arts education may be loosely understood as teaching and learning in or through the arts within a variety of formal and informal environments including Pre–K–12 schools, colleges and universities, community organizations, libraries and museums, cultural centers, or within one’s home or community. This entry explores the historical background, definitions, multiple purposes, critical perspectives, and connections to the now and the possible for arts education.

Keywords

Arts · Education · Arts Education · Aesthetic Education

Historical Background

In the English language, “arte” is the root of the word *artefact* or *artifact*. Artifacts often represent objects created by human beings within a historical or cultural context. Artifacts displaying a sense of artistry have been found to exist within the most ancient cultures throughout the world. From this prehistorical perspective, art can be understood as a means for our human ancestors to communicate, to chronicle and make meaning of their experiences, and as a mechanism for survival. More than serve these utilitarian purposes, since early times the arts have been used to make *special* (Sweeney, 2013) – or in other words, to make everyday objects, practices, and processes more interesting, unique, or distinctive. A design carved into a stone tool that would have otherwise had a strictly utilitarian purpose has been *made special* by the presence of that added design. The same may be said of a prayer sung in a unique

melodic tone and pattern or a garment adorned with colored dyes, bones, feathers, and beads.

Teaching and learning in the arts – arts education – has existed for as long as the arts have been a part of the human experience. Arts education long served as a platform for the transferal of the skills in creating artifacts within a historic or cultural context. So as with the trades, the arts have historically been taught through an apprenticeship model. In Japan, for instance, calligraphy, pottery, weaving, and Zen practices have all been taught in the past – and present – through apprenticeship (Singleton, 1998). Apprenticeship continues to be a powerful form of arts teaching and learning in many cultures around the world. Well-renowned composers, dancers, musicians, and sculptors have mastered their craft under one or more experienced teachers. In some cases, apprenticeships are formal arrangements that have rigid structures, and in other cases, an apprenticeship in the arts may be significantly less formal, more casual, or even embedded into one's daily experiences as part of being a member of a community or a tribe.

Beyond apprenticeship, arts teaching and learning has been taught more formally through schools and other learning environments. Many Western histories of arts education identify the East Coast of the United States as a forerunner in the development of such practices. Beginning in the 1800s, interests began to emerge in the training of young people to develop technical drawing skills. Training the hand and the eye in the practice of technical drawing had industrial applications that supported young people as they prepared for careers in various Industrial Revolution-era professions. One of the earliest texts (in English) noted to support technical drawing was *An Introduction to Linear Drawing* by William Bentley Fowle (1825). Fowle's book was an adaptation from an earlier French text, which he had translated into English for use in American public schools. While the city of Philadelphia and other east coast locales have been noted as early adopters of technical drawing and other forms of arts-related education, beginning in the 1860s the Commonwealth of Massachusetts was the first US state to formally incorporate the arts into the

public school curriculum. Although a complete chronology of the history of arts education is beyond the scope of this entry, many resources exist that provide such a background (see for example, Efland, 1990; Historical Perspectives in Art Education, n.d.; Soucy & Stankewicz, 1990; Whitford, 1923; etc.). Diverse in their narratives, what many of these chronologies of the history of arts education have in common is an origin story that grounds contemporary arts education in the practice of apprenticeship, specifically in regard to the time and place of the society in the form of art being practiced. From this perspective, arts teaching and learning emerged from utilitarian roots coupled with culture and history. This is true in the United States, as it is likewise true in other Western contexts, including the emergence of formal arts learning in many European settings.

Defining Arts Education

While arts education intersects with many other pedagogical practices (e.g., aesthetic education, the study of art history, instruction in arts appreciation, project-based learning, STEAM education, design- and maker-centered education, etc.), here, arts education is defined and discussed from the perspective of the institutionalized arts disciplines.¹ While viewing the arts from this perspective, it is important to note that there are multiple purposes for arts education. It is especially important to note that many of the purposes for arts education stretch beyond merely achieving mastery in a particular arts discipline. In a large-scale study of excellence in arts teaching and learning, Seidel, Tishman, Winner, Hetland, and Palmer (2009) surfaced seven different purposes for arts education. Among the purposes Seidel et al. identified are the fostering of broad dispositions and habits of minds; the development of artistic skills and practices (without making them primary); the development of aesthetic awareness; support for understanding the world; engagement with community, civic, and social issues; self-expression; and individual development.

Of course, grounding a definition of arts education in the arts disciplines requires a discussion of those disciplines. In this regard the very term “arts education” may be cause for confusion for some as the phrase “art education” (without the “s”) is perceived by many to relate to teaching and learning in the visual arts.² Alternatively, “arts education” (with the “s”) brings a plurality to the language that suggests teaching and learning in all of the various arts disciplines. For many, there are four disciplines that are covered under the umbrella term “arts education”: the visual arts, music, dance, and theater (see “Possible in Visual Arts” and “Possible in Performing Arts,” this volume). For many others, the arts disciplines further include the literary arts, media arts, and design (in all of its many forms, e.g., textile design, web design, fashion design, landscape design, etc.). Within each of these disciplines there are subdisciplines. For example, within the discipline of the literary arts there is poetry, fiction, screenwriting, playwriting, creative nonfiction, etc.

For the purposes of this entry, arts education is defined as teaching and learning in or through the arts disciplines, within any number of formal or informal educational contexts. Arts education may involve the direct instruction of the techniques associated with a particular arts discipline, the history of notable movements, works, and contributors to a particular arts discipline, the integration of the arts into the teaching of other non-arts disciplines, or the teaching of the arts to support cognitive development or greater, social, civic, political, or community-based change.

The Multiple Purposes of Arts Education

As noted previously, there is not one, but rather multiple purposes for teaching and learning in

and through the arts.³ Whereas some view the development of knowledge and skills within the arts disciplines as being the primary purpose for arts teaching and learning, others may view the development of knowledge and skills within the core content areas as being the primary purpose for arts teaching and learning. Others still may view a range of cognitive, social, or cultural outcomes as being the primary purposes of arts teaching and learning. Yet, there are many in the field who would not choose one of the above-mentioned purposes over another, but rather subscribe to the view that arts education serves a plurality of purposes (Seidel et al., 2009).

Arts Education to Advance Proficiency and Practice Within the Arts Disciplines

Perhaps the most straightforward and easy to comprehend understanding of the many purposes of arts education are those that subscribe to the development of skills and techniques associated with one or more of the arts disciplines. From this perspective, the goal of arts education may be to support an appreciation of a particular arts discipline, to support proficiency in that discipline, and perhaps to pursue mastery in that discipline. On one end of the spectrum, many elite conservatories and institutes of art have been established to foster mastery in particular disciplines, sometimes producing innovators in those disciplines that further their field. On the other end of the spectrum, many school-based, after school, and community-based programs have been established to offer arts education experiences with such discipline-based learning goals in mind – though with a much more casual, recreational, or self-enrichment spirit – often without the expectation of mastery.

Arts Education to Support Achievement in the Core Content Areas

Another approach to arts education uses the arts as a vehicle to support achievement in other

² Indeed, many of the historical accounts of arts education are grounded in an understanding of education in the arts as being an education in techniques associated with the visual arts.

³ For a broader discussion of the multiple purposes of arts education, see Seidel et al. (2009), as referenced above.

domains, particularly in the core content areas. Widely known as *arts-in-education* or more specifically expressed as *arts integration*, the goals of these approaches to arts education have less to do with pursuing proficiency or mastery within a given arts discipline, but more to do with supporting the proficiency of students in other subject areas (see, for example, Burnaford, Brown, Doherty, & McLaughlin, 2007; Burnaford, Aprill, & Weiss, 2013; Mishook & Kornhaber, 2006; etc.). Many advocates for arts integration might argue that the arts provide an entry point or an *on ramp* for students who may not excel in classrooms where the core content areas are taught in more traditional manners. This argument is predicated on the idea that the arts make teaching and learning experiences more accessible for young people and adults. In this regard, the *vehicle* of the arts may take many forms. A painting exercise may be used to teach abstract math concepts, a music exercise may be used to teach basic grammar, a dance exercise may be used to illustrate a scientific process, a theater exercise may be used to probe a historical event, etc.

Arts Education to Support Cognitive Development

Whether taught on their own or within the context of other content areas, there are many who argue that the primary purpose of arts teaching and learning is to support the development of an array of cognitive capacities (see, for example, “Creative Development,” this volume). This variety of cognitive capacities is sometimes referred to as *soft skills*, *dispositions*, *habits of mind*, or *noncognitive skills*.

Elliot Eisner (2002, 2003) was a professor of arts education at Stanford University and a fervent advocate of the arts, “the arts, when well taught,” he argued, “are fundamental in refining sensibility and cultivating the capacity to think imaginatively” (2003, p. 343). In 2002 Eisner published an influential text entitled *The Arts and the Creation of Mind*. Within this text, Eisner articulated ten lessons the arts teach that have often been used as advocacy points for arts education. Eisner’s ten lessons include (among others):

- “The arts teach children to make good judgments about qualitative relationships.”
- “The arts teach children that problems can have more than one solution and that questions can have more than one answer.”
- “The arts celebrate multiple perspectives.”
- “The arts teach students that small differences can have large effects.”
- The arts teach students to think through and within a material.”⁴

Consistent with the emphasis placed on the ten lessons the arts teach as articulated by Elliot Eisner, Lois Hetland, Ellen Winner, and their colleagues (2007, 2013) and Jill Hogan and her colleagues (Hogan, Hetland, Jaquith, & Winner, 2018) engaged in research to explore what they termed *the real benefits of the arts*. Here, the authors described the real benefits of the arts as thinking dispositions, which they refer to as *habits of mind*. Through their research, Hetland, Winner, and their colleagues have identified eight interrelated *studio habits of mind*. The eight studio habits of mind include the following: *Develop Craft*, *Engage & Persist*, *Envision*, *Express*, *Observe*, *Reflect*, *Stretch & Explore*, and *Understand Art Worlds*. While particular to the arts (and perhaps even more particular to the visual arts), each of the eight studio habits of mind delineated by Hetland, Winner, and their colleagues and Hogan and her colleagues is described as a thinking disposition that includes a set of skills, motivation to use those skills, and an alertness to occasion as to when to use those skills. While pertinent to the studio art classroom, the argument can be made that these eight studio habits of mind are transferable to other classrooms – or to other aspects of life and work.⁵

Contemporaries of Hetland and Winner, Shari Tishman and Patricia Palmer (2005, 2006, 2007) have likewise taken a thinking dispositions

⁵See <https://www.studiothinking.org/the-framework.html> for an overview of the Studio Thinking Framework.

approach to describe the benefits – or purposes – of arts education. Through their research on *Artful Thinking*, Tishman and Palmer likewise surfaced a variety of dispositions that are supported by arts instruction, and transferable to other domains. These dispositions, known as the Artful Thinking Palette, include: *Comparing & Connecting*, *Exploring Viewpoints*, *Finding Complexity*, *Observing & Describing*, *Questioning & Investigating*, and *Reasoning*. To support students and teachers in the development of their artful thinking dispositions, Tishman and Palmer have further developed a variety of *thinking routines*, short cognitive exercises, which may be used to “routinize” generative thinking dispositions grounded in explorations of the arts.⁶

Arts Education to Support Social, Civic, Political, and Community Change

Beyond the purposes of arts education associated with individual growth for students, there are those that further believe that one of the primary purposes of arts education is to spur social, civic, political, and community change (see, for example “Artivism,” this volume). From this perspective, the arts are seen as a means to protest and resist, as a means to assert one’s voice – or the voice of a community – and as a means to empower communities of people to pursue change. The intersection between these multiple change agendas and arts education is often described as *social justice and arts education* (see, for example, Bell, 2011; Garber, 2004; etc.). For many, the origins of social justice and arts education date back to the twentieth Century Civil Rights Movement. In reality, the arts – and arts education – have been leveraged for social justice purposes and used as an instrument of dissent for centuries – or even millenia. During contemporary times, social justice and arts education lies at the intersection of many different educational and social movements. And while the goal of social justice and arts education is to affect

change, the means to do so are by supporting students in understanding the injustices that exist in the world, in making those injustices visible, and in giving students a platform for their voice that they may not have had otherwise. In this way, the arts catalyze learners to speak up against injustices and to question what it means to participate in civic life. At times, issues of social justice and the arts take place on a national and international scale, but more commonly, arts education can be leveraged to support learners to address inequalities and injustices more locally.

Critical Perspectives on Arts Education

While there has been much written about the benefits of arts teaching and learning by many arts education advocates (see, for example, Fiske, 1999; McCarthy, Ondaatje, Zakaras, & Brooks, 2004; Seidel et al., 2009; Sinclair, Jeanneret, & O’Toole, 2009; etc.), education in the arts is not without its critics. Three popular critiques of arts education are that (a) it is a curricular frill that does not adequately support academic or cognitive growth, (b) that the dominant arts education narrative is biased toward the cultural interests of white, Western, patriarchal culture, and (c) arts education highlights the gap between the haves and the have nots, perpetuating inequality in learning.

Arts Education Does not Significantly Contribute to Academic and Cognitive Growth

Insofar as arts education is a brand of teaching and learning, many stakeholders across the edu-sphere would expect that it would yield significant academic and/or cognitive outcomes. Some critics of arts education, however, would argue that the arts do no such thing, particularly within formal schooling environments. While indeed it is the case that the arts taught for the sake of themselves within conservatories or esoteric institutes bolster proficiency in the arts disciplines, those who are more concerned with student proficiency in the core content areas may deny the value of the arts in the support of academic – or even cognitive

⁶See <http://pzartfulthinking.org/> for more information about the Artful Thinking Palette and associated thinking routines.

growth. In other words, the arts are viewed as an educational frill without any real academic value. Here, there is a fissure within the arts education field.

Some individuals that are staunch supporters of arts integration (see Sect. 3.2.) believe that the arts not only make education more accessible to young people, but they further support achievement in the core content areas. These individuals have argued that students who are taught the core content areas through arts practice attain higher test scores and generally enjoy increased academic achievement more so than those who are taught the same subjects through traditional non-arts methods. Despite the passion of such advocates and the persuasive arguments that they make, a metaanalysis of arts education studies claiming either causation or correlation between the arts and academic achievement found inclusive evidence for this argument (Hetland & Winner, 2001). This research supports the argument that the best way to teach math, science, or literature – is to teach math, science, and literature. The *real* benefits of the arts lie not in their residual academic effects, but rather in their cognitive and dispositional outcomes (see Sect. 3.3). That being the case, a more recent meta-analysis of research on the academic effects of drama-based pedagogy (a form of arts integration) offered contrasting findings (Lee, Patall, Cawthon, & Steingut, 2015). This study found that Drama-based Pedagogy had positive educational effects, especially in the English language arts and science classrooms, when taught under certain conditions.

That being the case, there are further critics of arts education who argue that the value of arts education does not lie in its potential to support intellectual or cognitive outcomes, but rather in its potential to support emotive or expressive outcomes. Here, a distinct line is drawn between the cognitive and intellectual benefits of arts education and the affective and emotive outcomes of arts education. While few will deny the latter, some contest the former. In 1967, Project Zero, a research center at the Harvard Graduate School of Education, was founded to directly take on this challenge. Led by the philosopher Nelson Goodman, Project Zero was established to study the

cognitive affordances of the arts (Gardner, 2013). Since its inception, researchers at Project Zero (and many of their colleagues) have argued against the claim that the arts are merely affective and emotive pursuits, but instead, that engagement in the arts and arts education has the potential to support many generative cognitive outcomes, including useful thinking dispositions and habits of mind (see, for example, Eisner, (2002, 2003); Hetland, Winner, Veneema, and Sheridan (2007); Tishman and Palmer (2006); etc.), that are beneficial within arts environments and in a host of non-arts settings.

Arts Education Is Biased Toward the Cultural Interests of White, Western, Patriarchal Culture

Over the centuries, as many European countries expanded their empires by colonizing other nations, they brought with them the art and cultural practices from their homelands. As Ballantyne and Burton (2005) write, “the impact of colonialism and the results of empire building are not restricted to ‘high politics’ and state practices, but also shape everyday life at a global level, influencing the languages we speak, the clothes we wear, the food we eat, the music we listen to, and the arts and culture we are inspired by” (p. 1). Since the fourteenth century, the world has become artistically connected as a result of European colonialism. The European conquest of countries around the globe – including the “third world” – has introduced imbalanced power structures within the arena of the arts and culture, just as it has within the social, economic, and political sphere. While local and indigenous art and cultural practices persist in many territories, European art forms have become the dominant form of arts practice for many others. Naturally, with an emphasis placed on Eurocentric arts practice comes an emphasis placed on Eurocentric approaches to arts education.

This brand of critique may further suggest that the biases inherent in the dominant arts education narrative play a role in perpetuating social inequities by “reify[ing] hierarchical conceptions of artistic practices in education and broader society” (Gaztambide-Fernández, 2013, p. 211). Within

the dominant arts education narrative, teaching and learning in the arts is often limited to the arts disciplines as defined by the Western canon (for a counter example see “Street Art,” this volume). From this perspective, arts education either positions non-Western heritage practices as being *less than* the Western arts disciplines, or by relegating them to the status of *craft* or *folk tradition*.

Arts Education Perpetuates Inequality and Promotes Elitism

Even within the West, there are those who argue that there is an inherent elitism associated with arts education, and instead promote the pursuit of maker-centered learning, or maker education. This critique of arts education foregrounds the idea that *making* takes many different forms within various social and cultural contexts. Deeming some forms of making as art (including all of its associations with European high culture) belittles all other forms of making, which have equal if not greater value within society, culture – and the classroom. In other words, whereas works made by artists are placed on pedestals and in gold-leafed frames, the work of craftsmen in their shops and seamstresses at their sewing machines are merely viewed as utilitarian goods that are produced not to be wondered at – but rather to be sold at market. In a popular quotation from *Art as Experience*, John Dewey (1934) makes an argument against the pedestal upon which the arts are often placed:

The intelligent mechanic engaged in his job, interested in doing well and finding satisfaction in his handiwork, caring for his materials and tools with genuine affection, is artistically engaged. The difference between such a worker and the inept and careless bungler is as great in the shop as it is in the studio. Oftentimes the product may not appeal to the esthetic sense of those who use the product. The fault, however, is oftentimes not so much with the worker as with the conditions of the market for which his product is designed. Were conditions and opportunities different, things as significant to the eye as those produced by earlier craftsmen would be made. (p. 5)

Dewey’s argument here is largely rooted in the distinction made between art and the craftwork of tradespeople, or more specifically, the “separation

of art from the objects and scenes of ordinary experience” (p. 6). At the heart of this distinction is the notion of aesthetics. While Dewey believed that there are aesthetic experiences to be found in one’s everyday interactions, the relegation of certain objects to art galleries and museums (and musical or theatrical performances to ornate opera houses, theaters, and concert halls) presupposes a hierarchy of aesthetics that differentiates between artful objects and experiences and the objects and experiences of everyday life.

The elitism critique of arts education extends into the domain of access and equity wherein many have argued that young people and adults from higher socioeconomic classes are likely to have more access to arts teaching and learning experiences than those from lower socioeconomic backgrounds. It is commonly understood that within under-resourced schools and communities, arts learning experiences are likely the first to be cut from the curriculum, whereas in more affluent communities and in sufficiently funded schools, arts teaching and learning opportunities are likely to be more abundant – and of higher quality (Tamer, 2009).⁷ This suggests that the arts – and arts education – are values of the upper classes – and that art education persists in environments that serve those social classes – to perpetuate the values and social standing of those classes.

With this foundational argument in place, one can make the connection between arts education and what Pierre Bourdieu and his colleagues (Bourdieu & Passeron, 1977) have described as *social and cultural reproduction*. In brief, the concept of social reproduction suggests that a particular social class of people endeavor to reproduce the conditions under which members of their social class thrive above others. Similarly, cultural reproduction suggests that a particular culture of people endeavor to reproduce the environment under which members of their culture can thrive above others. Education, from a Bourdieuan perspective, is seen as a vehicle for social and cultural

⁷While this is largely true, some have noted that science labs, sports equipment, and other such materials are just as likely to be cut from the budget in under-resourced schools and communities.

reproduction. Inasmuch as arts education may be viewed as being biased toward the interests of white, Western, patriarchal culture and a value of the higher social classes, then indeed arts education can likewise be viewed as a vehicle for social and cultural reproduction.

Connections to the Now and the Possible

Despite the critiques mentioned above, considering the now and the possible for the field of arts education opens up a vast opportunity space (see “Pedagogies of the Possible,” this volume). Not surprisingly, the now and the possible of arts education echo – and build off of – current ideas about arts education and our contemporary learning climate.

Hit with the 2019 worldwide pandemic, teaching and learning was forced to take place through nonphysical channels. Arts teaching and learning took on a new dimension, arts educators and students were pushed to reimagine, reshape, and reform. As it continues to evolve and adapt to a variety of teaching and learning environments, arts education continues to serve as a pathway to a host of possibility spaces. Below, six such possibility spaces (among many prospective others) are discussed: arts education as a connector across cultures and identities; arts education as a space to think between the disciplines; arts education as a vehicle for change; arts education as a provocation for innovation; arts education as an enactment of our humanity; and arts education as a means to tell our story to future generations.

Arts Education Supports Connections Across Diverse Cultures and Identities

In today’s highly connected world, the distances between cultures are much smaller than they were even a few decades ago. Contemporary technology, migration, and access to travel have enabled us to cross boundaries and widen the breadth of who we interact with, collaborate with, and within what environments and contexts we engage with one another (Seidel, 2013). As we cross parameters and boundaries through the interactions that we have each day, the different cuisines we enjoy,

the media we consume, and the people we see on the streets, we act as participants in culture in the form of both respondents to and bearers of a variety of cultures and identities. After spending time with a West African Ewe drumming ensemble, Sociologist Juliet Hess (2010) described her experience, “[m]y participation in an Ewe ensemble in Toronto demonstrates that cultures are indeed travelling musically. The question then becomes: when cultures travel, who or what is figured is refigured or remade and what becomes possible after the encounter?” (p. 157). The arts travel with cultures, and vice versa. The assemblage process of receiving the arts through our experiences, making sense of those experiences, and then sharing those experiences with one’s community describes the process of the arts (and arts learning experiences) serving as a connector across diverse cultures and identities. The possibility space for arts education, then, becomes the bridge that it may form across varied cultures and identities.

Arts Education Provides the Space to think Between and Across the Disciplines

While there has been much hype about STEAM education (adding the “A” for the arts to Science, Technology, Engineering, and Math (STEM) education), there is even greater value for arts education to provide a space for learners to make connections between and across the disciplines.⁸ Beyond merely combining a discrete set of disciplines, arts education may provide learners the opportunity to see the space that lies between the disciplines, and then to make connections across disciplines. In this regard, arts education supports the development of what may be understood as *multimodal thinking*. In other words, drawing on the multiple modalities of the disciplines as is necessary through the pursuit of an arts learning experience.

⁸For a critique of the STEAM agenda, see Clapp, Solis, Ho, and Sachdeva (2019). Complicating STEAM: A Critical View of the Arts in the STEAM Agenda. Retrieved from https://link.springer.com/referenceworkentry/10.1007%2F978-981-13-2262-4_54-1

Arts Education Serves As a Vehicle for Change

In an era where social injustices are ubiquitous, arts education has the potential to act as a vehicle for social change. Bell and Desai (2011) have stated, “social justice requires that as much as we use our critical faculties to grasp the complex and invidious ways that systems of oppression operate, we also need to engage aesthetic and sensory capacities so as to create and experiment with alternative possibilities – imagining what could otherwise be” (p. 287). The arts have long been a driving force in combating social injustices by delivering social and political messages in many ways. Arts education may serve as a means for learners to consider a social and political possibility space that is more equal, fair, and liberatory. As Bell and Desai have written, “[t]he tension between art and its social justice function is one that we cannot afford to treat lightly, especially if the arts are to give us the conceptual means to imagine and discover other ways of living together that are more equitable and just” (p. 290). Given the powerful role that the arts may play in addressing inequities, and the ongoing presence of such inequities within our contemporary world, then it is logical that arts education should be leveraged as a means to prepare learners to demonstrate and demand equitable social change.

Arts Education Provokes Innovation

Around the world, the arts and arts education are valued differently from one learning environment to the next. Too often, however, the arts are reduced to a marginal space in the curriculum. As Winner, Goldstein, and Vincent-Lancrin (2013) have stated, arts education remains marginal in many school settings but “education policies and initiatives based on arts education are gaining ground as a way to make education more innovative. Typically, these initiatives try to foster an innovative culture in teaching and learning in order to improve students’ academic outcomes but also creative dispositions and other social and emotional skills” (p. 25). Indeed, the world has a growing interest in innovation, with countries, corporations, and communities making increased investments in innovative programs

and practices. With this growing interest in innovation, one of the most powerful arguments that can be made for arts education is that, as noted in the OECD’s (2010) innovation strategy, the arts empower people to engage in innovation. The connection to arts education and innovation is usually made through *creativity*. Arts education advocates have long argued that arts teaching and learning experiences foster capacities and dispositions associated with creativity, imagination, and invention. To the degree that these same capacities and dispositions are essential to workers in the innovation economy, arts education may be seen as a vehicle to equip young learners for later careers in innovative industries.

Arts Education Facilitates the Enactment of Our Humanity

In our digitally mediated world driven by consumerism, corporate interests, and a 24-h news cycle, it may be easy to become swept up in the moment and caught in the flow of contemporary life. Somehow consistent with the fast pace of contemporary life is the ubiquity of the banal: cheap furniture, empty parking lots, packed freeways, and gut-rot gas station coffee.

Arts education may not be able to remove ourselves from the pace of this world or the banality of life entirely, but it can support us in finding a means to express our humanity. Whether for young people or adults, the arts, at their core, are expressive endeavors. Teaching and learning in the arts can not only support learners with the dispositions they will need to engage in the practice of aesthetics, develop higher order thinking skills, and speak up and speak out against injustices – it can also provide us with the capacity to express more of the intangible aspects about our inner selves and our lived experiences. Giving purpose to the things we make and experience – making life personal, uniquely experienced, and *special*.

Arts Education Informs How Will We Be Known in the Future

The artifacts of the past are how contemporary cultures come to know and understand the civilizations and cultures that have preceded them. In this way, the arts play a retrospective role –

providing a historical record of past human experiences. But the arts may also play a prospective role, too. The art that is made today has the potential to inform how contemporary societies and cultures are known and understood by the generations that will follow us tomorrow. Arts education, seen in this way, may be viewed as a means of documenting contemporary experiences to inform a future history that will reflect back on the now, telling the story of what it meant to be living in the world today. Arts Education, then, may equip learners to be the chroniclers of their experiences, the historical ambassadors of their cultures, and the ancestors of tomorrow. While there are many other means of chronicling contemporary experience for posterity (e.g., making a time capsule, keeping a diary, etc.), the arts flavor artifacts with expression, emotion, and a sense of aesthetic that tell a different story about what it means to exist today, perhaps more so than other more straightforward approaches to telling one's story – or the story of a collective people. A single artifact artistically crafted, unearthed decades, centuries, or millennia after its making, has the potential to connect experiences across time in a manner that is deeply subjective, sensory, and intimate. If art making has this sort of potential, then one of the possibilities for teaching and learning in the arts may be to prepare young people to not only aesthetically challenge and engage their worlds today, but also speak to the future tomorrow.

Conclusion

Arts education in its many forms is an integral part of a more comprehensive educational experience. From the origin of artifacts to the identified disciplines of the arts today, arts education has proven crucial to understanding humanity throughout history, provoking change, and documenting cultures and experiences. Arts education is, then, a core pillar to any kind of learning. It offers implications for the now and the possible in all formal and informal teaching and learning environments and further supports the development of the arts disciplines. It continues to open the door to new

achievements in already established arts domains, birthing the next generations of paradigm shifting artists, and shaping the future of aesthetics. Arts education may enhance student achievement in the core content areas, providing an onramp to success for students who may not have otherwise excelled in the classroom; arts education can support generative thinking skills and habits of mind that are cultivated in no other way – and it may serve as a platform for learners to develop their voice and speak truth to power. Beyond pushing further on current ideas about arts education, envisioning the future of arts education informs new purposes – and leads to greater possibilities. As Maxine Greene (1997), the often quoted philosopher of aesthetic education, once said, the arts provide us with the ability *to think of the world as if it could be otherwise*. In all of its variegated forms, if arts education teaches nothing else, it teaches us that very important lesson – the ability to see and embrace the world with all of its imperfections – and then imagine a much improved place that is just, and beautiful, and good.

"As If" Thinking

James Clack
University of Bedfordshire, Bedford, UK

Abstract

The notion of "as if" thinking is somewhat ill defined; it is used in a variety of contexts and, as a result, often has different or even contradictory interpretations. There are however commonalities across the literature that appear to suggest that "as if" thinking concerns the ability to think in some imagined context other than the reality that is presented in front – to think "as if" one is something or somewhere else and/or to use objects in unorthodox ways, different from their intended use. In this respect then, "as if" thinking is closely tied to imagination and ► ["what-if thinking"](#).

Across the empirical research, "as if" thinking appears to be the result of the interplay and resultant outcome of four key characteristics or capacities – ► ["imagination"](#), pretend play, abstraction, and empathy. These four capacities, when combined, provide the basis for an individual to experience multiple possibilities and realities through lived experience. This entry then provides an overview of the empirical research on "as if" thinking; outlines the role that imagination, pretend play, abstraction, and empathy each have in "as if" thinking; and explores the role that "as if" thinking has in relation to the possible.

Aaron: No one would have got my question ['Why did 100 people visit the library in May?'] [May was the highest month.]

Researcher: How would you answer your question?

A: Well, I kinda don't know, because it's a question about why did they go on [sic] May but not on a different day [sic]. . . It's just a weird question that I made up for some particular reason.

R: Yeah, it's a good question

A: Because why were there a hundred on [sic] May, they could have gone a different day [sic], couldn't they? (From Clack 2017, p. 63)

The transcript above comes from a Year 6 (ages 10–11) mathematics lesson. Children had been given a bar chart showing the number of visitors to a library over the course of 12 months and were then asked to devise their own mathematics questions. Expected outcomes were questions in the vein of the original task, comparing attendance in different months. Here however Aaron came up with a different type of question. Aaron was thinking about the data in a different way. He placed himself in the "real-world" scenario – *why* might there be differences in the attendances? What would I ask if *I* was the librarian?

There are Kantian roots to the notion of "as if thinking" (Schaper 1964) based around his notion of transcendental idealism. Transcendental idealism suggests we cannot know the "true" nature of reality, we can only know how it *appears* to us. As a result, "we are dealing with constructions and devices, with things that look *as if* they were something or other" (Schaper 1964, p. 220; original emphasis). Negotiating the real world requires us to accept that we can never know the "true nature" of reality; we only see things "as if" they were something else, and we construct our reality based on these interpretations. More recent discussions of "as if" thinking however have focused on child development while keeping the theme of seeing things "as if" something else. This "as if" thinking allows children to build a more concrete and complex understanding of the world. Indeed, "as if" thinking has been seen as part of the developmental stages in children's ► ["play"](#) forming a touchstone as their play – and their representations of reality – develops ever-increasing complexity (Bretherton and Beeghly 1989). In particular, it is in the context of play that the literature often explores the notion

of "as if" thinking; imaginative play, role play, pretend play, fantasy play, and so on appear to be necessary to "be in an 'as if' space" (Craft and Chappell 2014, p. 13).

Among the first authors to empirically describe and explore "as if" thinking in young children were Corrine and John Hutt (e.g., Hutt 1966; Hutt and Hutt 1989). In their research, they introduced children to unfamiliar objects and observed how their explorations of the objects changed with time and familiarity. They described this exploration as the move from "what is this?", the exploration of an object's physical characteristics, to "what can I do with this?", the use of the object in novel or unorthodox ways. Since then, the authors have sought to build on this work (e.g., Bretherton and Beeghly 1989; Chappell et al. 2008; Weininger 1986) and have explored "as if" thinking as distinct from "what if" thinking. Echoing Hutt's work, Craft describes this distinction as the move from "what is" to "what might be." Thus, "as if" thinking appears to be linked to different forms of "posing questions" (Craft and Chappell 2014), and research by these authors (e.g., Chappell et al. 2008) has sought to explore what type of questioning might result in "as if" thinking.

Despite this research, however, there seems to be little consensus on defining "as if" thinking across the literature. The term is often used without explicit definition or is mentioned within the context of other activity, perhaps as an outcome of some sort. Even within work by the same author, there can be differences from publication to publication – Craft, for example, describes it variously as "perspective taking," "being imaginative," and "question posing." What is possible, however, is to identify common features or capacities across the literature that are necessary, though individually not sufficient, for "as if" thinking. Imagination, pretend play, abstraction, and empathy each seem to have an important role in "as if" thinking.

Imagination and "As If"

Perhaps one of the foundational components of "as if" thinking is imagination; indeed, Craft and

Chappell (2014) have equated "being imaginative" with "as if" thinking (Craft and Chappell 2014, p. 13). At its most basic, imagination is the thinking process that drives play (Singer and Singer 2003) or "the thinking function of play... which sets the stage for the actual activity of play" (Weininger 1986, p. 25).

In addition to driving play, imagination – or imaginative play – also provides children with opportunities to develop, test, and explore familiar scenarios. This testing and exploring allows children to build, refine, or rebuild their working model of the world around them. As a result, imagination is often situated in real-world scenarios and linked with imitative behavior, such as role-playing in the "home corner" of a nursery classroom (Engels 2005). This imitative play creates a narrative for the child and allows them to build up their understanding of the day-to-day world and also to identify, reinforce, or reconstruct their knowledge and understanding of the boundaries between real and not real scenarios.

In providing the foundation for all play, imagination is therefore a necessary capacity for "as if" thinking. However, imagination is not sufficient for "as if" thinking. The process of "as if" thinking extends beyond imagination and toward the *actuation* of imagination. This we might describe as pretend play.

Pretend Play

Imagining – 'what if' – is a solitary activity within the child's mind, only sometimes overheard in actual words. Pretending – 'as if' – is usually done with other children, or for the child who has no one with whom to play, with imaginary people or dolls. (Weininger 1986, p. 28)

Pretend play, or pretence, appears too to be a central part of "as if" thinking. Children's early play may be largely imitative, repeating what they have seen in adult behavior or copying playful activities from more experienced peers (Russ 2003). Pretend play is more sophisticated and complex than imitative play as it involves "going beyond" imitative activity. Rather than recreating

existing realities, pretend play provides opportunities to create new, potentially unorthodox realities. Pretend play allows these new realities to be represented in action, a physical representation of the reality lived in the actor's mind. Building on the imagining of different possibilities, pretend play starts to put these imagined possibilities "into practice," often through assuming some related role or assigning of unorthodox or unconventional attributes to at-hand objects – a cone being used as a cup, a bowl being used as a hat, and so on.

This pretend play involves what Piaget describes as symbolic play – play using one object in place of another. Fein (1987) echoes Piaget, outlining pretend play as symbolic behavior in which "one thing is playfully treated as if it were something else" (p. 282). Symbolic play allows children to use myriad objects to represent their imagined narrative in the real world and to negotiate and reformulate these representations with those interacting in the narrative.

Pretend play therefore incorporates this symbolic play and "consist[s] of a child's understanding and representation of reality" (Weininger 1986, p. 22). Weininger suggests that this "real" pretend play "begins when a child uses a prop for something other than the activity for which it has been used with him by the caregiver" (ibid). Pretend play is the *implementation* of imagination, extending imagined ideas into new or unorthodox scenarios. Weininger describes this as the "as if stage" of play. Nevertheless, as with imagination, the ability to engage in pretend play is not necessarily synonymous with "as if" thinking. Pretend play, Bretherton and Beeghly suggest, allows children start to "perform very simple 'as if' enactments of routine events" (Bretherton and Beeghly 1989, p. 241). More complex examples of "as if" thinking go beyond pretend play and imagination. "As if" thinking appears to have a more abstract side to it: "more 'conceptual' playing or 'playing with ideas' rather than 'traditional' physical play" (Clack 2017, p. 66). To explore "as if" thinking further, we must also consider abstraction and empathy.

Abstraction and "As If"

The child's psychological world may contain more than the one distinction—real/not real. Children may make interesting and important distinctions within the pretend world. Once children narrate their play and tell stories, the as if world becomes multidimensional. It may well be that the 'as if' stance is a portal to a range of spheres of alternative realities. (Engel 2005, p. 515)

Abstraction refers to the process through which the features of, and relations between, objects are identified and experienced as separate from the concrete setting in which they are based, "something to do with the human ability to act independently in a world of objects" (van Oers 2001, p. 280) and "consists of taking information from the objects themselves, i.e., 'reading the features of a thing'" (p. 281). It is often conceptualized as some sort of "move" or "shift" – "moving" from concrete to the abstract and from abstract to the concrete (van Oers 2001), the "move" from "What is this?" to "what can I do with this?" (Hutt 1966), or the "shift" from "What is" to "what might be" (Craft 2008). The move from concrete to abstract has been described as "transposition-of-function" by Hutt (1966). Here, play occurs using tools and objects, during which time an "object explicitly fulfil(s) another function" other than its original intention or design (Hutt 1966, p. 70). This "transposition" is more complex than imitative and pretend play, advancing to a more representational form. Bretherton and Beeghly describe this as developing "counterfactual event representations," "moving" from the concrete to the conceptual (Bretherton and Beeghly 1989). That is, abstraction allows the child to "go beyond" their existing knowledge of a given scenario, formulate and reformulate their ideas, and act independently of real-world constraints.

Abstraction allows children to build an increasingly complex understanding of the world around them. It allows them to develop their understanding of real/not real, of possible/not possible, and builds a deeper understanding of the relationships between objects. Abstraction is a necessary part of "as if" thinking, but abstraction is not synonymous. For "as if" thinking, this "move" must be judicious. This takes empathy.

Empathy and "As If"

The above capacities each appear to be necessary for "as if" thinking: empathy – the emotional capability to consider how a situation might be experienced by another – appears to be the final capacity required by "as if" thinking (Clack 2017). The ability to empathize is an important developmental process for young children (e.g., Davis 1996), which improves as children better understand their experiences and the experiences of those around them. Indeed, the development of empathy appears to come from increasing participation in each of the three preceding capabilities (Hoffmann and Russ 2012), as pretend play and abstraction allow children to establish and negotiate rules with one another in different scenarios and roles. As the rules for these scenarios become more apparent, the actors begin to participate in an agreed-upon "imagined lived experience."

Craft highlights the importance of empathy, or "taking on another's perspective" (Craft and Chappell 2014, p. 1) when participating in "imagined lived experiences." An example of this may be seen in, say, children's play with wooden blocks, making constructions that change from cars to spaceships to unicorns as different children add to the on-going, changing narrative. It is important for each of the actors to acknowledge and understand the roles that other characters in the narrative play, in addition to understanding their own role to ensure that play flows smoothly. As what the blocks represent changes over time, each actor needs to "go with" this change and change their own role while also identifying the changing roles of others. In order to think or act "as if" in a narrative – to think "as if" they were that person – it is important to acknowledge the roles that other actors may have (Decety and Jackson 2004). That is, "as if" thinking not only requires imagining, pretending, and abstraction to create a new scenario, it also requires empathy with the scenario or character to understand how this scenario may form.

The identification of these four capacities appears then to help provide a meaningful basis from which we can start to conceptualize – and potentially identify – "as if" thinking. It is the

interplay of these capacities that leads to "as if" outcomes. Aaron's mathematics lesson, outlined at the start of the piece, provides an example for us to examine.

Aaron and "As If" Thinking

The vignette at the start of this chapter showed Aaron in a mathematics classroom but considering the problem set from an unorthodox perspective. Here, Clack (2017) suggests, is a compelling – though not unique to Aaron – example of "as if" thinking in the classroom. In this example, it is possible to identify each of the important capacities of "as if" thinking. We can see imagination – "going beyond" the original task and thinking of a new way to approach it. We can see pretend play – as Aaron assumes the role of a librarian. We see too abstraction – the "transposition-of-function" of the data, from mathematical task to contextualized scenario. Finally, we can see empathy – Aaron approaches the task with consideration of the types of questions that a librarian might reasonably ask. Note that this empathy goes beyond mere pretend play – it is not Aaron "pretending to be a librarian." Rather, it is Aaron "living" that experience.

Importantly, this example also shows that "lived" experience and "transposition-of-function" need not be a physical manifestation or manipulation. That is, "as if" thinking need not be evidenced through some recognizable role-play with objects per se, but may be realized through other less immediately visible means. As noted above, empirical research on "as if" thinking has often focused on young children (e.g., Chappell et al. 2008; Craft 2008; Cremin et al. 2006). These examples identify young children using objects in unorthodox ways – ways in which the objects were not originally designed. Aaron's activity shows how manifestations of "as if" thinking may differ or develop from younger children to older children – that "play" can be seen in a variety of ways and areas. This then allows us to start to conceptualize "as if" thinking beyond the current research that has largely focused on very young children. If, contrary to Weininger's

(1986) assertion, "as if" thinking does not occur only with others or with imaginary people, this opens up a new and interesting avenue for research.

"As If" Thinking, Creativity, and the Possible

"As if" thinking is not commonly discussed in the creativity literature. Of the many models conceptualizing creativity, one of the few that specifically highlights "as if" thinking as being part of the creative process is Craft's "Possibility Thinking" model (e.g., Chappell et al. 2008; Craft 2008; Cremin et al. 2006). Craft and her colleagues identify Possibility Thinking as the "driver" for creativity, central to which is the posing of questions. It highlights the importance of play to creativity and the notion of "moving" in some way, from a concrete, everyday scenario ("what is") to a more imaginative, abstract scenario ("what might be"). It is defined as, "exploratory transitions from 'what is' to 'what might be', encapsulated as the posing of the question 'what if?' in different ways and contexts, together with perspective-taking, or 'as if' thinking" (Cremin et al. 2013, p. 135). Possibility Thinking situates "as if" thinking as a driver for creativity when in combination with "what if" thinking – as necessary but not sufficient.

Again, while "as if" thinking does not feature heavily in much of the creativity literature, each of the capacities important to "as if" thinking has been identified as playing a role in the creative process. The role of play in creativity is well documented (e.g., Russ 2003; Lieberman 2014), as is the role of imagination (e.g., Duffy 2006). Russ has explored extensively the role that pretend play has in creativity (e.g., 2003, Hoffmann and Russ 2012), suggesting that, "the capacity to use fantasy and engage in 'as if' play behaviour should also be important in many domains of creativity" (Hoffmann and Russ 2012, p. 175). Similarly, as outlined above, numerous authors have explored the role of abstraction – "moving" from the tangible to the representational – as part of creativity; the ability to think of multiple new

scenarios and act both within and outside of the parameters of the original scenario has also been highlighted as driving creativity. Finally, Craft has identified "wise creativity" (e.g., Craft et al. 2008), highlighting the role of empathy within creativity. Thus while there is perhaps a lack of literature defining "as if" thinking, "as if" thinking does seem to play an important, if as yet unexplored, role in creativity.

Similarly, "as if" thinking appears to play an equally important, and similarly unexplored, role in the "possible." "Seeing" multiple possibilities and perspectives – *imagination* – is a foundational part of the "possible," whichever domain we seek to understand it (rt), and helps us "go beyond." Exploring possible worlds, possible selves, and possible pasts or futures all require us to extend our understanding beyond the existing concrete situation in which we situate ourselves. In other words, we need to *abstract* ourselves beyond the existing world as we explore further possible scenarios. To identify how these scenarios might play out, what the results or consequences might be, it is important to identify our potential role(s) in these scenarios; a way to do this may well be through *pretence*, either through physical play or mental conjecture (Kahneman and Tversky 1982). Finally, it is *empathy* that is required for us to understand how these scenarios relate to others in these scenarios and the role that they may play in this possible world. "As if" thinking then appears to play an important role in how we might understand and explore the notion of the "possible."

Summary

While there seems to be no agreed-upon definition of "as if" thinking, we can identify different capacities that are apparent when it occurs – imagination, pretend play, abstraction, and empathy. That said, there appears to be little consensus on the use of the phrase; it is possible to identify "as if" thinking, "as if" spaces, "as if" play behavior, and "as if" activity when exploring the literature around "as if." Furthermore, different authors place varying importance on the four capacities

of "as if" thinking. Bretherton and Beeghly (1989), for example, suggest that "what if" thinking is more complex and skillful than "as if" thinking; Weininger (1986) and Craft (e.g., Craft and Chappell 2014) appear to say the opposite that "what if" thinking is a precursor for "as if" thinking. Clack (2017) does not make a hierarchical distinction but distinguishes them by how they might be evidenced, with "what if" being more about physical manipulation and "as if" more conceptual.

Furthermore, the four capacities identified appear to overlap in description and function. The distinction between "imagination" and "pretend play" is not clear-cut in the literature, while Russ (2003) in her empirical work links imagination, pretend play, and empathy. The link between imagination and abstraction too is strong; Weininger (1986) suggests that it is only in how each is made visible that distinguishes them. It is not the case that these capacities should be conceptualized as distinct stages or ordered steps to the goal of "as if" thinking; rather they are presented as necessary to the process.

As with the literature on creativity, the literature exploring "the possible" identifies the importance of "as if" thinking but rarely provides explicit definition. The "possible," whether in relation to possible worlds, possible selves, or possible pasts or futures, appears to be driven by imagination and by abstraction of current scenarios into possible future ones. "Living" these possible worlds and understanding how they relate to others involve pretence and empathy. We can see the importance of the role then of "as if" thinking in the "possible."

Navigating the literature then is somewhat murky, and establishing a clear, concise definition of "as if" thinking upon which all authors and researchers might agree is challenging. Further empirical work aiming to identify and examine "as if" thinking may be needed to clarify these differences – or may muddy the waters further. Nevertheless, whether seen as developmental steps of increasing complexity, or as a progressive extension of imagination, outlining four aspects of "as if" – imagination, pretend play, abstraction, and empathy – provides us with a useful platform

from which to better understand and better identify "as if" thinking and its connection to the possible.

Definition

The multidisciplinary research field of automobility studies has articulated an alternative account and description of automobility to that which is routinely disseminated by an assemblage of automobility-related interests, in popular culture,

in advertisements, and by automobiles themselves. Automobility studies has opened up the possibility of developing a critical, alternative description of automobility, and the possibility of imagining a postautomobility future for our planet.

Introduction

The Oxford English Dictionary (3rd ed., entry for “Automobility”) defines automobility as “the use of automobiles or motor vehicles as a mode of transport.” It is an appropriate place to start, as “mode of transport” is how people unfamiliar with the term “automobility” are likely to initially understand the term. Dictionaries, however, as Martin Heidegger (1971, p. 172) once observed, “have little to report about what words, spoken thoughtfully, say.” This is so also in the case of automobility.

One can begin with the assumption that something called “automobility” exists “out there” in the world; the epistemological challenge then becomes how to analyze and describe “it.” Alternatively, one can begin with the assumption that what we understand automobility to be depends on how it has been defined and constructed in the first place: what it is, what its boundaries are, and what it is not. In everyday life, one way in which we understand automobility is as it has been defined by an assemblage of automobile-related interests.

“Philosophy,” Richard Rorty (1982, p. 226) once remarked, “is not the name of a natural kind but just the name of one of the pigeonholes into which humanistic culture is divided for administrative and bibliographical purposes.” “Automobility studies” is similarly a name for an administrative and bibliographical pigeonhole, identifiable through possession of what Wittgenstein referred to as a family resemblance. It is a community of scholars, research centers, and a bibliography that has challenged commonsense understandings of automobility. Automobility studies scholars have asked what those understandings are, where they originate, who they benefit, and what their consequences are. The automobility studies community not only has

articulated a critical, alternative account of automobility to that disseminated in advertisements, the mass media, by automobile manufacturers, within popular culture and public discourse, but also it has defined these representations of automobility as themselves intrinsic components of automobility and thus also as objects of inquiry and critique. Doing so raises the question of power: the capacity to define what automobility might or might not be – as simply a “mode of transport,” as nothing more than the materiality of automobility, cars, and infrastructure, for example. Whatever the validity or usefulness of these representations, these definitions *qua* representations are also components of automobility.

Automobility under its commonsense designations is a set of claims and assumptions regarding what automobility *is*. What distinguishes automobility studies is not only that it has articulated an alternative set of claims and assumptions, but also that “automobility” has been constructed as an object of theoretical and empirical inquiry. In offering an alternative definition of automobility, it has entered into the already existing politics of persuasion of automobility. The politics of automobility includes not only the obvious, such as the activities of automobile-lobbying organizations (Organisation Internationale des Constructeurs d’Automobiles 2019), but also ostensibly nonpolitical events, spaces, and activities, such as motor shows (Randell 2020a) and automobile advertisements which, in addition to attempting to convince us to purchase a specific automobile, endlessly reproduce the utopic visions of automobility that we routinely encounter each and every day. There is no nonpolitical epistemological location from which automobility could be represented “as it really is.”

What Is Automobility?

Whatever the usefulness, or otherwise, of a dictionary as a starting point, in everyday life automobility is experienced as more than simply “a mode of transport.” Cars are routinely experienced as “status symbols,” markers of social class; they are dangerous, under risk of death

and injury, they must be negotiated whenever we enter a road, whether in a vehicle or as a pedestrian or other road user; they have become a necessity; and they possess esthetic and other qualities that make them desirable, beauty and speed, for example. Automobility is experienced as providing freedom, convenience, and pleasure, properties that we take to be unremarkable, obvious, and commonsense. Automobility, in short, is a hegemonic order.

Not only has automobility constructed a world, but also we ourselves have been constructed as persons who want and desire automobility (Paterson 2007). We have come to possess an esthetic subjectivity, a Kantian faculty of judgment (Kant 2000), that experiences the socio-technical machines that are automobiles as beautiful objects of desire. Like the world that automobility has constructed, so have we been constructed as automobile subjects who, in the very acts of driving or passengering (Pearce 2016), are transformed into one component of a human-machine cyborg entity (Randell 2017).

With the initial appearance of automobiles on public roads at the turn of the twentieth century, automobiles provoked public opposition (Norton 2008). It was only in the mid-twentieth century that automobility began to be researched, theorized, and critiqued. In an essay first published in 1959 in *The New Yorker*, Lewis Mumford (1963, p. 220) observed that the US federal highways project required “slashing through old neighborhoods, stealing land from public parks, dumping traffic in urban centers.” The result of “the utopia that highway engineers have been busily bulldozing into existence” was impoverished urban and rural environments. John Keats’ (1958) *The Insolent Chariots*, which was on the *New York Times* bestseller list for 5 weeks, was a critique of automobiles, automobile manufacturers, road construction, death and injury, and the expense of automobiles. “We are,” Keats (1958, 158) wrote, “building a nation for automobiles rather than one for people.” Ralph Nader’s (1965) *Unsafe at Any Speed: The Designed in Dangers of the American Automobile* focused on American automobile manufacturers and the vehicles they manufacture. As the title made clear, it

was not, however, in Nader's view, all automobiles that were "unsafe at any speed" (cf. Braun and Randell 2020) but American automobiles. Below Nader's claims lay the assumption that there was such a thing as a "safe automobile," but it just did not happen to be an American automobile, which were unsafe because of design flaws that American manufacturers were well aware of.

What distinguishes contemporary automobility studies from these earlier critiques is having constructed a distinct object of empirical and theoretical inquiry, which is neither automobiles nor the collective singular noun "the car," but "automobility." The canonical texts of automobility studies have made the case for the existence of a *sui generis* entity – automobility – that is understood to be comprised of more, both materially and conceptually, than simply automobiles. Those components include, John Urry (2004) argued in a seminal paper, "The 'System' of Automobility,"

car parts and accessories; petrol refining and distribution; road-building and maintenance; hotels, roadside service areas and motels; car sales and repair workshops; suburban house building; retailing and leisure complexes; advertising and marketing; urban design and planning; and various oil-rich nations.

It is a list that can be infinitely expanded, to include tow-trucks, ambulances, operating theaters, undertakers, and funeral parlors; oil tankers and naval forces to protect oil supplies; and a geopolitical order that protects, upholds, and tacitly supports the human rights crimes of the regimes of the oil-rich nations mentioned by Urry. That also is automobility.

Steffen Böhm, Campbell Jones, Chris Land, and Matthew Paterson (2006, p. 3) in *Against Automobility* describe automobility as:

one of the principal socio-technical institutions through which modernity is organized. It is a set of political institutions and practices that seek to organize, accelerate and shape the spatial movements and impacts of automobiles, whilst simultaneously regulating their many consequences. It is also an ideological (see Gorz 1980) or discursive formation, embodying ideals of freedom, privacy, movement, progress and autonomy, motifs through which automobility is represented in popular and academic discourses alike, and through which its

principal technical artifacts—roads, cars, etc.—are legitimized. Finally, it entails a phenomenology, a set of ways of experiencing the world which serve both to legitimize its dominance and radically unsettle taken-for-granted boundaries separating human from machine, nature from artifice and so on.

The term "automobility," they observe, "has become recognized shorthand for referring to these different meanings" (Böhm et al. 2006, p. 4). How automobility studies are to be described and what automobility studies scholars understand automobility to be become, consequently, one and the same question.

It is against this theoretical backdrop that the components and properties of automobility have been described and analyzed across a spectrum of methodological and epistemological perspectives (Randell 2020b) in a now considerable and diverse corpus of empirical automobility research (Merriman and Pearce 2017). Encompassing political economy (Paterson 2007), cultural studies, the humanities, film studies, literary criticism (Pearce 2016), gender studies, race (Pesses 2017) and racial domination (Sorin 2020), Science and Technology Studies (STS), geography, law, and policing (Seo 2019), these studies have provided thick empirical detail and content to our understanding of automobility.

One can begin, as noted above, with the assumption that something called "automobility" exists "out there" in the world, or with the assumption that what we understand automobility to be depends on how it has been defined in the first place. The former, realist perspective, allows for epistemological disagreement – claims regarding what the properties of an already existing automobility might or might not be – between, for example, proponents and critics of "automobility." The latter, constructionist account, opens up the possibility to identify and empirically examine what, precisely, an assemblage of institutional agents (such as automobile manufacturers, state entities, and lobbying organizations) have been able to convince us to believe regarding what automobility is and what automobility is not; not only in respect to belief but also how we experience automobility, as a desirable, efficient, pleasurable, common-sense mode of transport, for

example. This represents a shift away from epistemology to ontology, not only the construction of epistemological claims but also the construction of an ontology, a world. So conceptualized, automobility may be described as a political ontology (Esposito 2021), namely an ontology which, to understand how and by whom it has been constructed, requires attending to power and politics, the latter in the widest sense of the term.

“A picture, Ludwig Wittgenstein (2009, § 115) wrote in *Philosophical Investigations*, “held us captive. And we couldn’t get outside it, for it lay in our language, and language seemed only to repeat it to us inexorably.” Automobility may be described as precisely such a picture. We cannot get outside it; we are convinced of its veracity. Through the combined activities of an assemblage of human and nonhuman agents, a utopic picture has been constructed that is repeated to us inexorably. The language within which automobility lies – in both senses of the word – is not only words but also cars themselves and the world they have created. It is this picture that automobility studies have challenged.

The Sociotechnical Imaginaries of Automobility

In *Dreamscapes of Modernity: Sociotechnical Imaginaries and the Fabrication of Power*, Sheila Jasanoff (2015: 4) defines sociotechnical imaginaries as: “collectively held, institutionally stabilized, and publicly performed visions of desirable futures, animated by shared understandings of forms of social life and social order attainable through, and supportive of, advances in science and technology.”

The history of automobility may be read as a history of a succession of sociotechnical imaginaries of the type defined by Jasanoff, each of which predicted a utopic automobile future, none of which came to pass as envisaged and promised. One of the more well-known examples is the Futurama exhibit in the General Motors pavilion at the 1939 New York World’s Fair (Jam Handy Organization 1940), which envisaged a safe and efficient automobility future located in a future

1960. Two contemporary examples are the electric vehicle sociotechnical imaginary and the autonomous vehicle sociotechnical imaginary (Braun 2019). They are regularly discussed and reported on in newspapers, on television, in trade publications, and in specialist automotive magazines, as well as in academic publications. They are promoted at motor shows and museum exhibitions (Braun and Randell 2021a). They are institutionally stabilized through the efforts of private and state actors. Embodied in prototypes and concept cars and disseminated in public visions of a desirable future, they are imaginaries, respectively, of a sustainable and accident-free automobility future. The technological fixes associated with these two imaginaries, we are being assured, will solve the problems of automobility’s contribution to the environmental crisis (Morton 2013) and road violence (Furnas 1935).

The assumption on which autonomous vehicles are being promoted is that automobile violence is not an intrinsic property of automobility but is contingent in that accidents are caused primarily by “driver error” (Braun and Randell 2020, 2021b). Neither automobiles, nor oil companies, nor automobile manufacturers are considered responsible for the charnel ground (Morton 2013, p. 126) that is automobility; rather, it is the driver who has been identified as the principal cause. Already in just the first two decades of the twenty-first century, 25 million people have been killed in what are routinely referred to as “accidents.” Each year, 1,350,000 people are killed by automobility and 50 million people are injured (World Health Organization 2018), and many hundreds of millions of animals are killed and injured (Davenport and Davenport 2006; Grilo et al. 2020). We can expect these figures to continue to rise, not fall, in the coming decades. It is estimates such as these that stand on one side of a moral equation, on the other side of which are the ostensible pleasures, conveniences, and freedoms automobility provides.

Each year, approximately 90 million new cars are manufactured, few of which are electric vehicles. Even on its own terms, by the time a global fleet of internal combustion engine automobiles would be replaced with electric vehicles, it will be

too late. Moreover, vehicles have their own demography. Electric vehicles do not replace internal combustion engine automobiles but push them “away” (Morton 2016) to the used car markets of the Global South, out of sight of the environmentally conscious inhabitant of the Global North. While electric and autonomous vehicles are promoted as solutions to two problems that superficially appear to be separate problems, namely climate change and road accidents, the two problems are identical: violence that results in death and injury (Braun and Randell 2021b).

“Sustainable automobility” is usually understood to mean ecologically sustainable, an automobility that no longer is based on fossil fuels. Another possible meaning of “sustainable automobility” is an automobility that is able to reproduce itself in the face of the harms it causes. Electric (automobility) is a case in point. Harms are caused “elsewhere,” in the mines of Africa or in hazardous waste collection facilities (EPA 2021). In continually promising futures wherein the problems of today will have been solved, the sociotechnical imaginaries of automobility contribute to the sustaining of automobility and its further expansion. As imaginaries of a future of safe and climate neutral automobility, they ensure the reproduction of automobility by offering a solution to which many have been convinced: the manufacturing of at least a billion new automobiles to replace the ones that currently exist. It is in this sense that we should understand the term “sustainable automobility.”

The Possible

There are two facets of “the possible” that automobility studies have opened up. First, in having articulated a critical and alternative account and narrative to the one that is inexorably repeated to us, it has performatively constructed an alternative account and description of automobility. The second “possible” that automobility studies has opened up is the possibility of living in a post-automobility world.

The alternative account of automobility, which is roughly the bibliography of automobility

studies, only fragments of which it has been possible to here mention or cite, is not limited to suggestions for remediating automobility, nor is it limited to criticisms of automobility such as the improbability that autonomous vehicles will reduce automobile violence in any meaningful way. Rather, it is an attempt to understand an entire way of life. In Heideggerian terms it is what Being-in-the-world might mean in the age of automobility in which we live (Randell 2017, p. 674), two measures of which are the total number of automobiles currently on the world’s roads (more than one billion) and the total kilometers of roads that to date have been built (64 million). “To understand our aesthetic experience of road traffic in the modern city,” Nigel Taylor (2003, p. 1611) has remarked, “is in large measure to understand our aesthetic experience of the modern city, period.” Much the same could be said of our entire planet.

One way to think about a postautomobility future is as a necessary but unwelcome future, as a loss that regrettably must be endured, not only, but also perhaps above all, due to the need to limit planetary greenhouse gas emissions, for which we are receiving our final warnings regarding the gravity of the climate emergency that is no longer located in the future but is already upon us. A postautomobility world would be not a world where the automobile has simply been replaced by equally oppressive mobility technologies. That too would be no different from what now goes under the name “automobility.” Postautomobility is not a world of connected, electric, autonomous automobiles, nor would it be a world of “flying cars,” another of the many sociotechnical imaginaries of automobility.

Another way to think about a postautomobility world is as a better world than the one we currently inhabit, not as a constraining and unfortunate necessity. A world where the urban and rural spaces that have been appropriated by and for automobiles (McShane 1994; Norton 2008) have been reclaimed for other purposes; a world absent the routine violence of automobility; a world the natural habitats and resources of which are not being systematically depleted and destroyed; a world where there is room for other species and

beings besides ourselves; a world in which the world itself is not being terminally destroyed.

Yet another way to imagine postautomobility is as an entirely different political ontology to the one that has been constructed by the human and nonhuman agents mentioned above. It would be a different ontological constellation of power and politics, a different world than the one we now inhabit.

Summary

Automobility studies has articulated an alternative, critical account of automobility to that routinely disseminated by an assemblage of automobility related interests. This has required making visible the violence that is routinely occluded within the automobility imaginary. Automobility studies has made possible the development of an automobility politics directed towards bringing a post-automobility future into existence (Braun and Randell 2022a, b).

Autonomy

Elisa Kupers¹ and Linda Hendriks²

¹University of Groningen, Groningen, The Netherlands

²Hanze University of Applied Sciences, Groningen, The Netherlands

Abstract

The concept of autonomy has received considerable attention in both –philosophy and psychology. From the perspective of philosophy, autonomy refers to self-governance of one's actions. In psychological theory, the focus has been more on human beings striving to experience autonomy and self-determination. In this entry, we will examine the elusive concept of autonomy from different theoretical angles and focus in particular on how autonomy emerges through social interactions and how

it develops over the course of the lifespan. We will pay special attention to the role autonomy plays in creativity and the exploration of the possible.

Keywords

Autonomy · Agency · Social interactions · Creativity · Possible

People can be self-driven, taking initiatives and shaping their own environment, or they can be helpless or hesitant, governed by authorities and unable to make their own decisions. What exactly does autonomy entail, and how does autonomy play a role in interacting with the possible? Is autonomy a more or less stable personal characteristic, or is it different in different situations?

In this entry, we will discuss the well-known yet elusive concept of autonomy both from philosophical and psychological perspectives. We will briefly discuss the empirical research on how autonomy might be a central feature of “being human” and of human's psychological thriving. Autonomy will be discussed further not only as a central human “trait” or characteristic, but more as an enacted, dynamic property that emerges in the interactions humans have with their social and material environment. This will bring us to connecting autonomy not only to the interaction with the “here-and-now” but also to the interaction with the possible and with creative processes.

Different Theoretical Perspectives on Agency and Autonomy

Both agency and (personal) autonomy have been explored extensively in philosophy. “An agent is a being with the capacity to act, and agency is the manifestation of this capacity” (Schlosser 2019, p. 1). According to some definitions, agency can only be called agency if it is fully intentional, driven by intentions or desires, and in line with one's attitudes. That would imply that only humans can act with full (or higher-order) agency. However, agency can also be seen in a broader

sense. Not only (human) mental states such as beliefs and motives can be a cause for action, but also drives such as hunger or aggression. That would mean that agency is not a uniquely human concept and can also be displayed by non-humans.

One widely agreed upon part of the definition of agency is that agency involves the *initiation of action* by an agent. It is exactly this initiation part of the definition that links agency to autonomy. An agent is one who acts; autonomous agents are self-governing agents. Because no one else can initiate actions other than the agent herself, all agents can be said to exercise self-governance or autonomy (Buss and Westlund 2018). But what does self-governance entail exactly? Sometimes one is forced to do something by some external authority. Sometimes someone does something “in spite of herself,” as a result of internal conflicting forces, such as a recovering addict pouring herself a drink, although she had sworn to never to drink again. Although an action cannot be performed without it being initiated by the agent, there are certainly cases where this self-governance is at a bare minimum because the behavior is determined not by the agent’s own (conscious) motives but by other forces. In such situations, autonomy in the sense of self-governance is merely a formality.

In the area of psychology, autonomy has been known through the theoretical work on personal causation (de Charms 1968) which was later further developed in self-determination theory (Deci and Ryan 1985, 1991). De Charms observed, as we will discuss further down this entry, that human beings develop from not being able to distinguish between the self and others, to discovering more and more their capacity to exert effects in their environment. Psychology on motivation had, until then, mainly focused on goals that people set for themselves and the efforts they exert to obtain these goals. De Charms saw the *desire* that human beings have to be causal agents as the underlying principle underneath specific goal setting and goal-directed behavior: “Man’s primary motivational propensity is to be effective in producing changes in his environment” (de Charms 1968, p. 269). As a consequence, he also saw a

crucial role for *the experience* of causal agency in one’s behavior. In other words, it does not really matter whether, in a given situation, there was true self-governance over one’s behavior, as long as the person experienced a sense of freedom and autonomy in determining their own actions. The attribution of causes is important: persons can perceive themselves as causal agents (or “origins” as De Charms puts it) or as being governed and “pushed around” by external forces (as “pawns”). This perception of self-governance or autonomy can differ per person, but also within persons. One can feel an autonomous agent in one situation and a helpless pawn in another.

Following the work of De Charms, self-determination theory embraced the perception of autonomy as a key feature in distinguishing between different kinds of motivation. Types of motivation can be placed on a continuum ranging from being completely extrinsic (such as acting upon reward or punishment) to being more internalized. The most optimal form of motivation is motivation that is truly intrinsic and in accordance with one’s own motives and desires. The theory further states that in order to achieve this kind of intrinsic motivation, three basic psychological needs have to be met: the need for autonomy, competence, and relatedness. The need for autonomy refers to the need to have a sense of control over one’s actions, to not be passively “steered” by others in one’s environment but instead to feel self-driven; to act in accordance with one’s sense of self. The other needs are the need for competence, which refers to the need to feel able to reach the goals one has set for herself and the need for relatedness, which refers to the universal human need for a sense of belonging to one’s social environment, to make deep and meaningful connections to the people around oneself. The needs are not entirely separate; indeed, the need for autonomy is “woven into” the other two needs. For the need of competence, for example, only goals that are autonomously chosen or embraced by oneself, truly result in feelings of genuine competence. Autonomy can be said to be the underlying dimension that gives fulfillment of the other two needs true meaning (Deci and Ryan 1985, 1991).

The fundamental difference between the philosophical and the psychological perspective on autonomy is that self-determination theory (or the psychological perspective) is mainly or exclusively interested in the extent to which human beings *experience* autonomy, regardless of the more philosophical question of whether humans *are* in fact self-driven. Consider the extent to which a student in a classroom feels autonomous. Instead of the teacher giving one assignment for all students, she lets the students choose whether they want to complete the standard test on the subject, or whether they want to challenge themselves more by making a more complex assignment. The student chooses the challenging assignment and completes it successfully. A philosopher might comment that this situation still poses many constraints (the choice of the student might be random instead of fully intentional, many of the choices are already imposed by the way the educational system works, the teacher only provides two choices, and perhaps she might even subtly nudge the more accomplished students towards the more challenging assignment). That would mean that the student's actions and choices are not truly self-governed and therefore not completely autonomous. From a psychological perspective, although the environmental constraints and enablers are certainly noticed and subject of investigation (see later on in this entry) what in the end matters is whether the student *experiences* a sense of autonomy in this situation.

The Development of Autonomy

Research in developmental psychology, most notably the fundamental work of Piaget, sheds light on how we develop into more or less autonomous individuals. The foundations for agency lie early in infancy (Siegler and Alibali 2005). Piaget stated that the newborn is mainly governed by reflexes, but that their actions soon, already after the first months, become more and more intentional. After a few months, infants already show a very rudimentary form of agentic action. They perform an action; feeling a blanket, grasping

their parent's finger, experience the sensation, and repeat it. Piaget called these "primary circular reactions." Later, after about 4 months of age, these cyclical actions are expanded to not only their own bodies (feeling, grasping), but also the world around them (for instance, kicking a mobile, watching it move, kicking again). Although it would be too early to ascribe goals to infants, in their repetition of manipulations to the world around them already a very rudimentary, embodied sense of agency emerges. The agentic actions are still very much connected to the here-and-now and elicited directly by aspects of the physical world close to them. These agentic attempts become more precise, elaborate, and coordinated over time.

An important change occurs around 12 months of age, when young toddlers begin to intentionally vary their behaviors: when they drop a ball on the floor repeatedly, for instance, they alter the altitude of the fall, alternate between dropping and more forcefully throwing behaviors to observe the different effects. This change is especially relevant when linking agency to the possible: by varying their actions intentionally, children explore *what could be done* with an object, rather than repeating intentionally what has been done before. They seem interested to find out what variations produce different effects. Indeed, divergent thinking tests have been developed for children as young as 2 years old where divergent thinking is operationalized in a non-verbal and embodied way, as the extent to which children vary their agentic actions and explore "new" possibilities of objects through these actions (Bijvoet-van den Berg and Hoicka 2014). New has to be seen in the "mini-c" meaning of the word, that is, a new discovery for the child herself but not necessarily for others. This interaction with the possible, but still very much grounded in the physical and social environment of the here-and-now, is the prelude to the development of pretend play, where children explore possibilities that are more and more moving away from the current, grounded reality and more towards stretching the boundaries of reality and (im)possibility (the block of wood is a car, I am a dinosaur).

Next to the developing *capacities* to act more and more agentically, in interaction with the current and the possible, there is also an increased *desire to act autonomously* throughout childhood and adolescence. In fact, one might think of child development as an increasing exploration of who one is, and what one can do, by themselves and out of their own choice. This striving is more pronounced in some developmental phases than in others (and of course, more pronounced in some children than in others). Parents will recognize the infamous “terrible twos” as a period where children are often exercising their autonomous will and desire to practice with capacity for self-governance (expressed by saying “no” to their parents’ demands and “I do it myself” often). Another developmental phase that is known for the desire for increased autonomy is of course adolescence. In this phase, the child is able to see more and more possibilities for oneself, and is more conscious of the different possibilities for identity development, increasingly independent of their parents. Their exercising autonomy and desire for more self-governance fits that picture (McElhaney and Allen 2012).

Autonomy as Socially Constructed

Autonomy does not develop in a social vacuum. Rather, there are many constraints and enablers within any given situation that either allow the emergence of a deep sense of autonomy or that can in contrast hinder one’s feeling of autonomy. In theory and research on autonomy, much emphasis has been laid upon social influences on (perceived or observed) autonomy.

In Interpersonal Theory, agency is viewed as one of two core dimensions of people’s interpersonal behavior. In interactions between two (or possibly more) people, the persons engaging in interaction display agency in their behaviors to some extent. In the interpersonal sense, the emphasis is not so much on the extent to which behavior is truly self-governing, but more on agency relating to roles in the interpersonal interaction. An important principle here is complementarity on the agency dimension (Gurtman

2001). One of the parties is initiating, leading, proposing, which elicits following, listening, or undergoing behavior from the other person. Importantly, although persons can develop a “style” of interacting with others, recent research shows this enacted agency in interpersonal interactions is dynamic and fluid; a person can be leading in one moment and following in the next, much like a dance where the roles are not fixed and leading and following alternate (Sadler et al. 2009; Pennings et al. 2014). Interestingly, research on patterns in interpersonal interaction also shows that occupying alternating roles in interaction give rise to exploring possible states of interacting with one another, and that more flexible dyadic interaction patterns where multiple possible states of communication are explored give rise to more advantageous outcomes (Granic et al. 2007), although studies on these mechanisms relating this specifically to autonomy are currently lacking.

Concluding, autonomy can be seen as a state rather than a trait, and more specifically, a state of being that emerges through co-regulated social interaction. The experience of autonomy, therefore, has its roots in these emergent social interactions, characteristics of which can either enhance or inhibit the personal experience of autonomy. It is perhaps not surprising that a great deal has been done to uncover how autonomy can best be promoted or cultivated, in particular in education, parenting, and in work environments.

Cultivating Autonomy

A large body of research on how to cultivate autonomy exists especially in the area of education. Teachers and other significant figures in children’s environments, through their interactions with students, can support students’ autonomy in order to stimulate their motivation, agency and engagement with tasks in a meaningful way (e.g., Reeve et al. 2004; Reeve 2009; Vansteenkiste et al. 2005; Cheon et al. 2020). Although autonomy refers to the feeling that one’s actions emanate from oneself and are one’s

own (Deci and Ryan 1987, p. 1025), students are in many situations still dependent on support from a more competent other (Ryan and Deci, 2006). The example at the beginning of the entry, of the student being able to choose their own assignment, is one illustration of how autonomy can be fostered by the teacher who at the same time provides structure by narrowing down to two relevant options.

“Autonomy support” refers to an interpersonal approach taken to help students experience learning as relevant to their self-determined goals and interests and to help them realize these goals and interests (Assor et al. 2002). Autonomy support nurtures students’ meaningful engagement with tasks and stimulates their agency in several inter-related ways. Stefanou et al. (2004) distinguish among organizational, procedural and cognitive autonomy support and stress the importance of the latter. First, autonomy support is student-centered and entails offering students the space for their own discoveries (Deci et al. 1994). This involves questioning and inviting students to explore and provide time for this. Stefanou et al. label this approach cognitive autonomy support as it provides students ownership of their learning. Offering time to think and observing students while they are exploring, affords teachers to monitor the learning process and ask relevant follow-up questions. Secondly by providing organizational autonomy support (Stefanou et al. 2004) teachers can provide students with ownership of environment by offering them relevant choices concerning with whom or where to work, implementation of criteria and rules, and so on. Offering procedural autonomy support generates ownership of form and this involves a.o. choice in tasks, materials, task approach and how to display results. Third, autonomy support is associated with welcoming, informational and non-controlling language (Reeve 2009) which expresses showing respect to students (Stroet et al. 2013). Supporting children’s autonomy this way encompasses stimulating children to imagine possibilities and engage in meaningful activity in a creative process where goals are

emerging and are taking shape, along with the material results of their endeavors.

Despite the benefits of autonomy support shown in research in educational settings, teachers tend to adopt a low-autonomy supportive, controlling style of teaching during instruction time (Reeve 2009). A controlling style is teacher-centered and involves imposing the teacher’s own perspective on students’ thoughts, feelings and/or actions, as well as the exercise of pressure (Reeve 2009).

Autonomy, Creativity, and the Possible

As stated before, a key feature of the development of human autonomy involves the agentic exploration of the possible. The discovery of having control over oneself, and the ability to manipulate the environment goes hand in hand with the exploration of the different possibilities of exercising this agency: first embodied in the manipulation of the physical world, but soon already in pretend play and hypothetical thinking. Linking this to creativity, we can see clear relationships between the agentic exploration of the possible, real or imagined, and idea generation (see Creativity, this volume). Continuing this reasoning, we can see divergent thinking as agentic exploration of the possibilities that are the least obvious.

The concept of “possibility thinking” was coined in the early 2000s to describe the practices children and teachers engage in in classrooms and which are believed to be key to creative thinking in schools. Possibility thinking comes down to a shift between focusing on “what is this and what can it do” to “what could this be and what could I do with it.” Possibility thinking includes posing questions, engaging in play, immersion and making connections, being imaginative, innovation, risk taking, and self-determination (Cremin et al. 2006; see also Possibility Thinking, this volume). By engaging in possibility thinking, the child is *agentially engaged* in exploring possibilities and generating novel ideas. However, creativity encompasses more than just the stage of idea generation. Just as agency in interpersonal

communication involves an alternating dance between leading and following, creativity involves both being pro-active and agentic, initiating actions and ideas, but also listening to others, observing, evaluating (especially in collaborative forms of creative performance, such as jazz, dance, and theatre improvisation, see Sawyer (2000)). Indeed, even professional creatives working alone describe being “taken over” by their own work of art, and being in a flow where they follow the lead of the creative work-in-progress. (see, Inspiration, this volume).

The literature on stimulating possibility thinking and creativity in education shows remarkable resemblance with the literature on autonomy support. Profiling learner agency is key in fostering creativity: students should be provided with multiple opportunities where they can initiate their own actions, students are encouraged to be active and independent, to take risks and to experiment (Cremin et al. 2006; Sawyer 2017). In classrooms where creativity blossoms, the usual classroom dynamic where the teacher is the authority figure and students are following, is abandoned. Instead, pedagogy is student-led rather than teacher-led and teachers often consciously “stand back” to let students figure things out for and among themselves.

But also here, there is more to it than just providing a lot of autonomy support for students to not only engage with the possible at the level of exploration, but also at the level of deeper engagement with possibility and creative ideas. Sawyer (2017) notes the tension that exists between allowing students freedom and standing back on the one hand, and providing structure and guidance on the other hand. Not all students fare equally well with completely open-ended assignments and ill-defined problems. The careful balance between fostering students’ autonomy at the right times and putting in boundaries, constraints, and evaluations is necessary for “productive” and deep exploration of different possibilities. This providing structure could on the one hand help to narrow down an overwhelmingly large landscape of endless possibilities. On the other hand, the teacher can also help by guiding students into exploring a broader

horizon of possibilities than they had imagined by themselves.

Summary

To conclude, autonomy is a key element of engaging with the possible. Agentic exploration of the possible, in interaction between oneself and one’s physical and social environment, is a cornerstone of human functioning and development from a very early age onwards. The desire to experience autonomy in one’s actions is uniquely human and an important drive behind exploration of the possible. That does not mean that agency should be experienced all the time. In interaction with the here-and-now, as well as in interaction with the possible, agency and autonomy can be seen as a dance where leading and following alternate.

Avatars

Stéphanie Buisine¹ and Jérôme Guegan²

¹CESI, Nanterre, France

²University de Paris, Paris, France

Abstract

Avatars are virtual characters that now belong to the popular culture around video games, social networks, and digital applications in general. However, using an avatar may not be as insignificant as it seems, because avatars, by providing us with a fresh new appearance, may impact the very perception of our own identity. The aim of this entry is to offer an overview of the sociocognitive processes influenced by the use of avatars and illustrate them with empirical findings from the literature, including examples related to the Proteus effect. Finally, we will open avenues as to what could become possible through avatars, in particular in the field of avatar-mediated creativity.

Keywords

Avatar · Proteus effect · Virtual world · Self-perception · Deindividuation · Creativity

Avatars are digital characters, often customizable, representing users' identity in a virtual environment (Meadows 2008). They are projections of users, or "tangible embodiment of their identity" (Ducheneaut et al. 2009). Users can create avatars looking like them, experience a multiplicity of identities or highlight certain aspects of their ideal self (Bessière et al. 2007). Thereby, the configuration of avatars allows users to change their appearance, their social roles, and their identity in the virtual world. The relationship between users and their avatars may even provide support to engage people with lifelong disability in activities

and social interactions (Stendal et al. 2012). A recent line of research has also shown that users' behaviors are influenced congruently to their avatar's identity. This behavioral modulation was named Proteus effect (Yee and Bailenson 2007, 2009) after the Greek God Proteus who possessed the ability of metamorphosis.

At a theoretical level, explanations of the Proteus effect are primarily rooted in self-perception theory and deindividuation effects. Self-perception theory argues that individuals come to "know" their own attitudes, emotions, and other internal states partially by inferring them from observations of external cues, which include their appearance and overt behavior (Bem 1972). Individuals observe external cues on themselves to explain their own attitudes and internal states, just as an external observer would. This is why a change in self-representation (e.g., through an avatar) may lead to a change in behavior. Moreover, self-perception reliance on identity cues (and therefore on avatar's appearance) is likely to be enhanced when individuals find themselves in contexts of anonymity and deindividuation (see Yee et al. 2009). Deindividuation refers to situations in which people are not identifiable as individuals (e.g., in large groups, but also in a virtual world, see Postmes and Spears 1998), and therefore experience a loss of self-awareness. This was shown to moderate the impact of contextual cues on individual behavior (Spivey and Prentice-Dunn 1990; Yee et al. 2009).

Because avatars constitute "our entire self-representation" and virtual contexts emphasize reliance on cues related to the visual appearance of one's avatar, the Proteus effect leads users to exhibit behaviors and rationalize them so as to remain consistent with the avatar's identity (Yee and Bailenson 2007). Instances of the Proteus effect have been found in various avatar-based systems, influencing a diverse range of decisions and behaviors (for a recent review, see Ratan et al. 2019): for example, attractive avatars lead to behave in a more intimate way in terms of self-disclosure and interpersonal distance (Yee and Bailenson 2007; see also Waddell and Ivory 2015). It should be noted that this phenomenon results from the mere exposure to a virtual mirror

allowing the participant to see his/her avatar for about 1 min. In this respect, it can be considered that the Proteus effect is initiated almost instantly. In another study, Yee and Bailenson (2007), Yee et al. (2009) have shown that tall avatars lead to more confident behavior than short avatars in a negotiation task. Recent studies have also shown that the appearance of the avatar may affect subsequent behavior in the real world (Yee et al. 2009; Rosenberg et al. 2013; Yoon and Vargas 2014). For example, the benefits of a tall avatar on negotiation endure in a subsequent negotiation task in a face-to-face situation (Yee et al. 2009). Likewise, it was found that the weight of avatars influence real life physical activity during motion gaming sessions (Peña et al. 2016; Peña and Kim 2014). This means that the appearance of an avatar influences users' behavior not only in the virtual world, but also in the real world.

Beyond behavior, it has also been shown that avatars could influence attitudes and productions of the users. For instance, the embodiment of female avatars, with an appearance more or less sexualized, can impact perceptions and judgments toward women (Fox et al. 2013), and the use of a doctor versus a Ku Klux Klan avatar can influence the content of stories composed by the users (Peña et al. 2009).

Another line of reasoning argues that the effect of avatars' appearance on users may also be explained through priming (Bargh et al. 1996; Peña et al. 2009). According to Bargh et al. (1996), priming refers to "the incidental activation of knowledge structures, such as trait concepts and stereotypes, by the current situational context" (p. 230). Avatars could then be seen as a priming support leading to behavioral assimilation, i.e., an increase in the likelihood of behaviors congruent with the primed concept. For instance, embodying an avatar whose appearance is likely to activate antisocial concepts (e.g., violence, aggression, racism) could lead to behave in a more negative way.

It was shown that avatar appearance in video games impact subsequent aggressive cognition. For example participants displayed more aggressive attitudes and intentions toward other players when their avatar wore a black cloak – a color

associated with death and evil (Adams and Osgood 1973) – than when they wore a white coat (Peña et al. 2009, Study 1). Eastin et al. (2009) found that White players displayed more postgame hostile thoughts after having embodied a Black avatar than a white avatar. Ash (2016) showed that players embodying a Black avatar in a boxing game exhibited greater aggressive in-game behavior than those embodying a White avatar. However, this effect was only present for players experiencing high levels of embodiment.

Moral orientation of the embodied character – heroic versus villainous – also impacts post-game behavior. Happ et al. (2013) showed that participants who had embodied Superman exhibited greater prosocial behavior and less hostile perception bias than those who had embodied a stereotypically evil character – the Joker. Rosenberg et al. (2013) showed that embodying an avatar possessing superheroes' powers (flying) volunteered more to help the experimenter pick up pens he had dropped than those who had flown as passengers of a virtual helicopter. Finally, Yoon and Vargas (2014) asked participants to play a game, embodying Superman or a villainous avatar (Voldemort), and then to take part in a blind test of food – taste a dish and add an unspecified amount of chocolate (prosocial action) or chili sauce (anti-social action) for consumption by a future participant. Participants who had embodied Superman behaved in a more prosocial way than those who had embodied Voldemort.

The influence of avatars on users who embody them is now well established in the literature, and this effect may impact users' behavior and/or attitudes, both online and offline, for better and worse. Hence, this body of research suggests that a targeted use of avatars bears the potential of supporting the achievement of high goals and the opening of possible futures. In the following section, we address more particularly the issue of increasing creativity through the use of avatars.

Avatars, Creativity, and the Possible

In this series of experiments, we used avatars to modify self-perception in order to improve one's

creative performance. To do so, the first step was to identify what kind of avatars would likely increase the perception of one's creative skills. These experiments being conducted with engineering students, we studied the cognitive representation of creativity in this population. This led us to identify the concept of the Inventor as a common relevant creative figure for engineers (Guegan et al. 2016). Accordingly, we designed and validated avatars featuring characteristics of inventors (e.g., looking like Einstein, wearing a lab coat or using scientist's instruments). We expected that users of these avatars, observing their digital appearance ("I embody an inventor"), would make implicit inferences about their creative skills ("I am creative") and improve their creative performance ("I have a lot of ideas/good ideas"). Consistently, our results show that engineering students using inventor avatars during a virtual brainstorming session performed significantly higher in fluency and originality in comparison to students using neutral avatars and students in a face-to-face electronic brainstorming situation (Guegan et al. 2016). Moreover, this benefit endured over time since participants allocated to inventor condition continued to perform higher in a subsequent face-to-face brainstorming. Subjective data also showed that brainstorming in a virtual environment (either with a neutral or a creative avatar) was rated as funnier than electronic brainstorming system.

The previous experiment managed to increase creativity by making engineers identify with the figure of the inventor. In terms of innovation process, this is likely to emphasize engineers' talent to develop products of superior technological value and therefore support a Technology-Driver strategy (Jaruzelski et al. 2014) representing high degrees of R&D difficulty (Mantelet et al. 2016). Then we wondered whether avatars could be used to help engineers develop User-Centered innovations, motivated by customer needs instead of technological value. To investigate this question, we designed a case study with a major company from the transportation industry.

A group of highly qualified employees from the innovation department were attributed inventor avatars like in the previous experiment, and

another group was attributed avatars representing users of public transportation (Persona avatars, e.g., a mother with a newborn, a child, an elderly person, a train manager). Both groups were immersed in a transportation situation (metro tour across a virtual Paris) and had to find applications for smart windows in public transportation. As expected, the content of ideas was influenced congruently to avatars' appearance: the inventor condition led to a techno-centered ideation profile, oriented toward technological solutions, while the Persona condition led to more user-centered, needs-oriented ideas (Buisine et al. 2016). Consistently, inventors' production tended to be better evaluated through industrial criteria and Personas' production tended to be better evaluated by transportation users. These results suggest that avatar-mediated brainstorming could be a powerful tool enabling innovation team to align ideation to their strategy (e.g., technology-centered or user-centered).

Beyond self-perception and personal identity, avatars may also be a convenient medium to emphasize social identity in a virtual environment (e.g., Guegan et al. 2015). Social identity is defined as a part of self-concept linked to group membership (Tajfel and Turner 1979). In this way, a positive evaluation of one's in-group may contribute to a positive evaluation of the self, leading people to work as a group and for the group and exhibit increased performance (i.e., social laboring, Haslam 2004). Hence in a subsequent experiment, we introduced social identity cues on avatars' clothes as it could be implemented in various professional contexts (e.g., clothes in the colors and logo of a company, sport team jerseys). On the basis of the Social Identity Model of Deindividuation Effects (Reicher et al. 1995; Spears and Lea 1992, 1994), we assumed that virtual cues would exert a positive effect on group performance (see Tanis and Postmes 2008). By perceiving themselves as members of a group rather than coworkers who are "gathered together," individuals should be more likely to engage in online collaborative work. The results confirmed this assumption by showing that social identity cues on avatars' clothes increased both group identification and creative performance (Guegan et al. 2017). Hence avatars appeared as

a valuable tool to reduce social loafing and support teamwork in a meaningful way (see also Buisine and Guegan 2020). Moreover, in the context of a creative assignment, group identification may influence not only the perception of group members ("we" instead of "I"), but also of their ideas ("our production" instead of "my production"). Because attention to others' ideas is key to creativity (Paulus and Brown 2007; Michinov 2012), increasing the salience of social identity may also improve cognitive stimulation.

The use of avatars may therefore open up the field of possible in the context of group brainstorming: group facilitation is similar to electronic brainstorming system and can be conducted remotely through the instant messaging tool of the virtual platform. The facilitator can be represented by an avatar like all participants, or can manage the group without being embodied or materialized in the virtual world. Classical efficiency factors such as cognitive stimulation and social comparison are supported and can be further enhanced with relevant avatars' appearance. Moreover, virtual sessions were repeatedly evaluated as fun in all our experiments, which may contribute to foster engagement and creativity. Virtual brainstorming can also involve large groups to promote diversity of views and increase cognitive stimulation, as there is potentially no limit to group size in a virtual world. Idea generation is still performed through the written channel to avoid production blocking and improve attention to others' ideas. Finally, avatars provide a unique means to stimulate creativity through modifications of individuals' perception of their personal and/or social identity, thereby reducing social loafing and self-censorship to help everyone reveal his/her best creative potential.

Conclusion

Avatars have the advantage of triggering self-perception mechanisms that may positively impact creative processes in multiple ways: anonymity and the use of carefully chosen avatars may reduce self-censorship and social loafing, to the benefit of creative performance and innovation

strategies of companies. Avatars sharing social identity cues can help group members focus on team's issues and challenges, and create social laboring. They can also be used to infuse new dynamics, promote a new viewpoint, and change routines (e.g., hierarchical asymmetry, interpersonal relations, leadership) among regular coworkers. All these factors seem likely to help individuals develop their creativity, support innovation processes in organizations, and, more generally, build the possible.

Awe

Alice Chirico

Department of Psychology, Università Cattolica del Sacro Cuore, Milan, Italy

Abstract

If experiences of profound transformation have a core moment, that can be awe, an emotion able to maximize the possibility to **change** especially through its self-transcendent nature.

Awe arises from stimuli so vast to prompt people to go beyond their current schema. Awe would drag people into a deep moment of **uncertainty** in which *assimilation* process fails, but *accommodation* has not successfully taken place yet. In this middle-suspended moment of extreme potential, everything might occur. This entry started with the current psychological definition of awe; then, it summarizes main researches in this field. Finally, I outlined the transformative nature of this phenomenon – as a self-transcendent emotion – and a new perspective to frame it in relation to a sense of *possibility* to **change**.

Keywords

Awe · Transformation · Change · Possibility

Definition

Awe is usually conceived as a positive emotion arising from circumstances able to shake our mental frames due to the vastity of the knowledge they tale with them (Keltner and Haidt 2003). This emotion denotes a fracture in people’s accustomed way to see themselves, the world, and others, which leads to several impacting consequences at the individual and at the social level. If this operational definition may look straightforward and clear, the path, which has led to this, has been not.

Etymologically, the English word “awe” derives from Middle English, as a substitute of the word *agi* in Old Norse. This term referred to a mixed feeling of fear and reverential respect imbued with **wonder** that people experience in response to a powerful Other (i.e., person or something divine). Along with philosophical perspectives on awe (Burke 1844; Kant 1989), which highlighted the importance of the negative fearful component of this emotion, also early psychological contributions on awe (Hall 1897; James 1902; McDougall 1908) strongly endorsed a negative nuance of this emotion. However, lately, with psychological work of Keltner and Haidt (2003), the negative side of awe gradually disappeared – in line with the current usage of the word – and attenuated the component of fear (Bonner and

Friedman 2011). Currently, its meaning is closer to **wonder** and reverence (Sander and Scherer 2014), with a more positive definition and use of this term with few exceptions (e.g., Sundararajan 2002). As Bonner and Friedman stated (2011) “Although earlier psychological understandings of awe routinely described elements of fear as predominating, more recent descriptions appear to deemphasize fear [...] it now appears that the concept of awe may be seen as related primarily to experiences with positive emotional valence, but for some the term may still have connotations of fear or even terror, or a combination of both positive and negative emotional valences” (p. 225).

Despite researchers still struggle to define the nature of this emotion, most agree that awe can be conceived as the core of profound **changes** in life (Bonner and Friedman 2011; Chirico and Yaden 2018; Miller and C’de Baca 2001; Pearsall 2007; Schneider 2017; Skalski and Hardy 2013; Yaden et al. 2017). Particularly, psychologists devoted the last 20 years to analyze the process underlying this **change** as well as the consequences of awe for human well-being and progress (Chirico et al. 2016). To systematize this rich corpus of studies, it is possible to identify two main perspectives adopted within psychology to elucidate the nature and effects of awe. First, the experimental approach has shed light on the pro-social potential of awe, on its impact on the sense of time, on mutual connectedness, attentional focus, ecological behaviors, body perception, sense of agency, endorsement of spiritual beliefs, creative thinking, and knowledge seeking (for a review see Chirico et al. 2016; Chirico and Yaden 2018). Overall, awe has been considered as a sparkle of unexpected **change** through different stages. For instance, Valdesolo et al. (2016) already configured awe as peak moment of an epistemological process stemming from surprise, **curiosity**, and **wonder**. Awe would emerge as a key driver of knowledge restructuring or conceptual **change**. More recently, Nelson-Coffey et al. (2019) suggested and showed that other **emotions** revolve around awe, such as compassion, optimism, gratitude, awe, and love within the domain of self-transcendence. Awe can lead to transformative **change**, but it is still not clear how and why. This aspect has been elucidated more in

detail by the second corpus of studies, which mainly relied on a qualitative paradigm of analysis of awe. Psychologists – often, but not only – adopted a phenomenological approach (Gallagher et al. 2015; Reinerman-Jones et al. 2013; Smith 1996, 2008; Smith et al. 2003) which described the process and the dimensions a *transformative* experience of awe is composed of (e.g., Gallagher et al. 2014, 2015; Pearsall 2007; Reinerman-Jones et al. 2013; Weger and Wagemann 2018).

Beyond the methodological approach, most studies agree that awe could stimulate connectedness among people, a mutual sense of belonging, an expansion of the sense of time (Bonner and Friedman 2011; Gallagher et al. 2015; Otto 1958), and other transcendence-related dimensions. Specifically, most researchers analyzed the transformative side of awe by framing up this **emotion** as a self-transcendent experience (e.g., Chirico and Yaden 2018; Nelson-Coffey et al. 2019; Stellar et al. 2017; Yaden et al. 2017) promoting a sense of small self and connection. These studies evidenced that awe can prompt people to look beyond mundane concerns and towards the universe, in which we look like no more than fine dust. Probably, by expanding the array of possible worlds, awe can *maximize* the possibility to **change**.

As a ripple in a pond, awe may act as a central node of transformation, by transcending current view of the world, thus maximizing the possibility to **change**. This entry started with the current psychological definition of awe, before summarizing main researches in this area. The transformative potential of this **emotion** as a self-transcendent **emotion** and a new perspective to frame up it in relation to a sense of possibility is proposed.

Research on Awe

Crafting a discourse on **emotions** is a privilege since it means describing and studying the most complex and pervasive phenomena orienting human behaviors, decisions, and relations in the subtlest way. Despite their strength, **emotions** remain fleeting phenomena fading away so soon that it is so hard to capture all their nuances.

Therefore, describing an **emotion** starting from its main reference scientific model could turn into a mere rhetoric practice. Instead, the lived experience of an **emotion** coming from its first experiencers could be a more effective source of information on it. It could be truer in the case of a complex and rare **emotion** such as awe. To provide a first glimpse into the rare but pervasive nature of this **emotion**, it could be suitable to choose two examples from the religious and the secular domains.

Regarding the religious domain, the conversion of St. Paul on the road to Damascus is considered as a prototypical case of “awe.” St. Paul realized that God was talking to him. First, he lost his sight. Then, he was filled with a sense of disorientation and sudden awareness that his entire life had been devoted to pursuing the wrong purpose. The loss of sight was the metaphor for the spiritual bankruptcy of the whole pre-Christian system. A further example of awe is depicted in the well-known book of Charles Dickens *A Christmas Carol* which describes the unexpected transformation of the miser Ebenezer Scrooge when he realized that the treasure of life was not money but people. It is not surprising that this **emotion** has accrued the interest of many scholars across years. However, unexpectedly, psychology has started devoting attention towards this **emotion** only 16 years ago, thanks to the seminal work of Keltner and Haidt published on the journal *Cognition and Emotion* in 2003 (p. 297). Authors described this **emotion** as process stemming from two core components deemed as main appraisal themes of this **emotion**:

- (i) *Vastness*: this dimension refers to the perception of stimuli as perceptually and conceptually vast. Therefore, both limitless natural views, as well as the grasping of a complex theory (e.g., the String Theory), could be potential elicitors of awe.
- (ii) *Need for accommodation*: the need to transform current mental frames according to new information.

However, it can be possible to introduce variations of these central appraisal themes, thus

giving forth other emotional states. Specifically, Keltner and Haidt identified other four additional emotional themes that can “flavour” (p. 304) the experience of awe, giving rise to different awe-related states:

- (i) *Threat*: awe is tinged with fear when it arises from something perceived as dangerous. This dimension borders on the feeling of *sublime*. According to Kant (1914, 1989), a key component of the sublime is facing a danger from a safe existential position. This negative dreadful nuance of awe was investigated by psychology only recently (Gordon et al. 2016), and results were promising, suggesting considering the sublime as a close instance of awe.
- (ii) *Beauty*: aesthetically beautiful inductors can dye awe with a sort of aesthetic pleasure. This component was considered as crucial in the field of psychological **aesthetics** (Konečni 2005, 2011, 2015; Schindler et al. 2017), and it has been often considered as close to the sublime (Konečni 2011). Konečni considered Aesthetic **awe** as the prototypical response to sublime *in-context* stimuli.
- (iii) *Ability*: the encounter with incredible instances of talent and ability, let the **emotion** of **awe** turn into the closer feeling of *admiration* for them (Onu et al. 2016).
- (iv) *Virtue*: when we meet examples of extraordinary morality, such as Gandhi, **awe** turns into the near emotional state of *elevation* (Haidt 2003; Shiota et al. 2017).
- (v) *Supernatural causality*: this is the least clear component of the model and the one which has been least investigated in psychology. Authors stated that this additional appraisal theme would appear when we are in front of something almost improbable if not **impossible**, such as the view of Goddesses. It is also possible to imagine many kinds of physical law violations (e.g., law of gravity) as conductive to this kind of **awe**-nuance.

Notably, these new appraisals can tinge **awe** with both positive and negative valence, which are not mutually exclusive but could coexist

(Chirico et al. 2017). In other words, the unusualness of **awe** as an **emotion** dwells on its natural flexible valence, which places it beyond the boundaries of conventional **emotion** models (Chirico et al. 2016) and asks for new and integrated methodological paradigms of analysis of **awe** (e.g., Nelson-Coffey et al. 2019). Consequently, both qualitative and quantitative approaches have been adopted to elucidate the nature of this complex **emotion**. To take stock of the increasing number of studies on **awe** and of the related methodologies, it is possible to identify two main approaches. On the one hand, researchers mainly relied on an experimental approach and looked at (i) peculiar mechanisms underlying this **emotion**, (ii) at its behavioral, (iii) physiological, (iv) neural correlates, as well as its (v) link with other cognitive or emotional processes. On the other hand, studies drawing more from a qualitative – mainly phenomenological – analysis of this **emotion** focused more on the dimensions of **awe** and the process of **change** it stems from (Stellar et al. 2017).

Both approaches evidenced that the transformative nature of **awe** realizes mainly by means of its two main self-transcendence properties, that is, a sense of being small in front of something transcending the self, i.e., the “small self” effect (Piff et al. 2015), and feeling connected, i.e., sense of connection, with the world and beyond (Nelson-Coffey et al. 2019; Saroglou et al. 2008; Stellar et al. 2017; Van Cappellen and Saroglou 2012; Van Cappellen et al. 2013; Yaden et al. 2016). Specifically, **awe** can relieve people’s concerns towards themselves and shift their attention from themselves to others (e.g., people and nature). Then, **awe** would promote a sense of deep connection with the surrounding (again, people or nature or the universe), thus repositioning individuals in their rightful place in the world. In the following, the self-transcendent nature of **awe** will be unpacked according to the phenomenological and the experimental approaches on this **emotion**.

At the level of studies adopting mainly a qualitative paradigm of analysis, the self-transcendent nature of **awe** emerged in terms of specific phenomenological dimensions. For instance,

Bonner and Friedman (2011) analyzed six interviews transcribed by Schneider in his book (2009) and evidenced that the most meaningful moments in life were marked by the presence of this **emotion**.

The phenomenological dimensions are detailed below.

- (i) “Profoundness”: **Awe** resulted as a profoundly meaningful experience.
- (ii) “Connectedness”: This self-transcendence-related dimension refers to a deep sense of mutual connection with something bigger than us.
- (iii) “Numinous”: It has been described in detail by Otto (1958) as an irrational dimension of religious experience. It arises from the perception of something holy and transcendent.
- (iv) “Fear”: It was less frequently reported.
- (v) “Vastness”: Both physical and conceptual sense of being in front of something bigger and larger than as. It is closely related to the sense of connection previously described.
- (vi) “Existential Awareness”: People in **awe** become suddenly aware of their existence in the world, by experiencing a sense of “presence” within the space and time they inhabited.
- (vii) “Openness and Acceptance”: People reported to be more open to others and to be more able to accept the death and human limits.
- (viii) “Ineffable Wonder”: Being in **awe** was like the mark of being alive, as a part of the mystery of life.
- (ix) “Presence”: **Awe** was experience as a “break” in life where people could focus on themselves and on important things.
- (x) “Heightened Perceptions”: People reported to be more respective. They perceived stimuli as more vivid and salient, as if they were transported to another level of reality.

To conclude, **awe** emerged as an experience able to make people transcend their current way to “stay” in the world, to look at it, and perceive it as well as other persons.

To use a technological metaphor drawn from **Virtual Reality** (VR), **awe** experience is close to when users chose to grasp a virtual object, and it takes one too many steps, thus going outside the area tracked by the VR device. Suddenly, it appears a grid to signal that user's movements are going too much beyond the virtual world. The simulated nature of the virtual world becomes salient and clear in that moment. The same happens with **awe**. **Awe** signals that we are going beyond and reminds users that there is always more, beside the simulation we have been accustomed to.

Probably, it is not by chance that, nowadays, **Virtual Reality** (VR) – 3D computer-generated environment in which the user can navigate and can manipulate (Riva and Waterworth 2003, 2014; Waterworth et al. 2010) – has resulted as one of the most effective methods to study the rare experience of **awe** within the limited spaces of a lab (Chirico et al. 2017). **Virtual Reality** provides researchers and people with the possibility to be immersed within a simulated world, which is completely manipulated and in which users' movements can be fully tracked along with their physiological parameters. Therefore, if Bonner and Friedman (2011) were able to exploit secondary data coming from spontaneous lived experiences of **awe** (Schneider 2009), experimental researchers cannot long for the same in the lab. To this end, experimental research has devoted effort not only to study **awe**-related effects in a controlled way in the lab but especially to improve the induction methodology of such complex **emotion**, in order to grasp its **transformative** potential for **cognition** and human change (Chirico et al. 2017; Chirico et al. 2018a, b, c; Chirico and Gaggioli 2018; Chirico and Yaden 2018; Chirico et al. 2016).

First, researchers focused on the use of *videos* and *images* to study **awe**'s self-transcendent nature. Several studies explored the pro-social function of **awe** as a proof of its self-transcendent essence (Akin et al. 2014; Bonner 2015) at the state and dispositional level (Li et al. 2019; Piff et al. 2015; Stegemoeller 2016; Stellar et al. 2017; Zhang et al. 2014). **Awe** served a pro-social function since it could enhance generosity and

supportive behaviors even towards unknown people (Prade and Saroglou 2016). Specifically, it has been shown that the experience of **awe** can promote pro-social attitudes as measured by the amount of money participants would give to others in donation tasks or by their willingness to help even unknown people in need (Prade and Saroglou 2016). Furthermore, **awe** would entail action tendencies and a shift of one's attention towards others (Stellar et al. 2017). This leads to a decreased sense of self-entitlement as measured by subsequent feelings of self-diminishment in front of **awe**-inducing stimuli, also known as the "small self" effect (Piff et al. 2015). Consequently, people in **awe** are more prone to take care of others' well-being, that is, to show pro-social tendencies. Moreover, a diminished sense of self turns into an enhanced feeling of humility (Stellar et al. 2018). Also, even negative or abstract forms of **awe** promote pro-social tendencies (Piff et al. 2015). This happened also when people share an experience of **awe**, that is, when they were told to be living this experience jointly with another person (Stegemoeller 2016). At the dispositional level, trait **awe** promoted pro-social behaviors not only in Western culture (i.e., USA and Europe) but also in East cultures, such as in China (Guan et al. 2019). Moreover, Zhao et al. (2018) demonstrated that **awe** makes people more generous not only towards other people but also to the natural environment. **Awe** would promote pro-environmental behaviors by attenuating people's dominance over nature, probably supporting a feeling of connection with it. Also, at the physiological and (Hu et al. 2017) neural level (Hu et al. 2019), it was showed that people tended to reduce attention to the self and devote more attentive resources towards others and the world during **awe**. All people in **awe** can feel relief from mundane affairs and thus pay less attention to materialistic pursuits such as money (Jiang et al. 2018); they are prompted to look beyond the immanent towards the transcendent. This approach would turn into a deeper meaning of life – i.e., lives are coherent, significant, and imbued with a feeling of transcendent aim (Snyder and Lopez 2009) – which would nurture an increased satisfaction towards life (Zhao et al. 2019).

This “openness” towards even unknown others emerged also at the cognitive and trait level. **Awe**’s cognitive impact is in line with Fredrickson’s (Fredrickson 1998) “broaden-and-build” theory on positive emotions. Fredrickson posits that positive emotions can expand our thought-action repertoire, a crucial asset for self-flourishing and survival (Shiota et al. 2017). **Awe** expands attentive focus (Sung and Yih 2015). Sung and Yih (2015) showed that even experimentally induced **awe** could expand our frames of reference to promote cognitive accommodation of the **complexity** of a stimulus. Crucially, **awe** *enlarged* people’s mental models more than other positive emotions, which are often considered as pivotal for knowledge acquisition, such as “interest” (Sung and Yih 2015). Moreover, **awe** makes people less swayed by persuasive messages because it prompts seeking more information against or in favor of proposed argumentations (Griskevicius et al. 2010). This aspect emerged also from the brief work of Valdesolo et al. (2016) showing that **awe** led (at least atheist) people to endorse more supernatural (vs. evolutionary) explanations beyond scientific explanations. At a trait level, **awe** was found to be positively correlated with extraversion and openness to experience personality traits (Shiota et al. 2006; Silvia et al. 2015). These studies evidenced that, **awe** “*expands*” people’s mental frames both in terms of *width* and *depth*. **Awe** prompts to look for new information outside our usual domains of interest and to deepen the existing ones, in order to achieve an innermost understanding of the world, of others, and ourselves. **Awe** expands our *possibilities* to see the world and surrounding to an extent that Valdesolo et al. (2017) indicated this **emotion** as one of the drivers of knowledge-restructuring or conceptual **change** process. **Awe** would be at the core of the process of science learning (Valdesolo et al. 2017). **Awe** motivates explanation-seeking as a function of the degree of **uncertainty** that is inborn in **awe** itself. Specifically, these authors speculate that **awe** arises from events violating our expectancies, showing a salient gap in our previous knowledge. **Awe** is responsible for a feeling of deep **uncertainty** and a subsequent desire to acquire more

information to avoid this feeling (Valdesolo et al. 2017). This urge is called “need for accommodation,” and it is also one of the two main appraisal themes at the base of **awe** (Keltner and Haidt 2003). It is the prompt to move from a knowledge-enriching process to a knowledge-restructuring one or cognitive **change**. The need for accommodation component has a proxy, that is, the feeling of **uncertainty**. People who were prone to live **awe** displayed also a more flexible way of thinking and were more able to manage **uncertainty** (Shiota et al. 2007). On the other hand, experimentally induced **awe** reduced participants’ ability to deal with **uncertainty** (Valdesolo and Graham 2014). **Awe** itself is a destabilizing **emotion** with a disruptive power to de-structure people’s mental frames. It may be possible to state that **awe** places people in a *liminality* zone (see Horvath et al. 2015 for a definition) conducive to **change**.

This aspect has been firstly captured and studied experimentally in a recent study on the effect of **awe** on *creative thinking*. Creative thinking can be defined as the ability to recombine ideas and to discover new links among them (Guilford 1950; Torrance 1969, 1974). In this study, **awe** was elicited by means of a *basic VR format, 360° videos*, and compared with a neutral **emotion** (Chirico et al. 2018c). Participants primed with **awe**-eliciting videos reported higher abilities to think in flexible, original, accurate ways after a single exposure compared to those who had watched neutral videos. Crucially, exposure to **awe** predicted increased creative thinking. In other words, VR-induced **awe** allowed demonstrating, for the first time, that **awe** can expand our perspectives towards the same objects, thus potentially amplifying our creative vein. Again, **awe** pushes beyond the fixed schema or accustomed view of the world and prompts to look over.

Conclusions

If transformation has a core moment, that can be **awe**, an **emotion** able to maximize the possibility to **change** by means of its self-transcendent nature. **Awe** makes people explore the impossible

and unpredictable because it prompts to go beyond current situations, schema, or frames of the world. This happens, as suggested by Gaggioli (2016), because **awe** would drag people into a deep **uncertainty** moment in which *assimilation* process failed, but *accommodation* has not successfully taken place yet. It is like a middle-suspended moment of extreme potential, in which everything might occur.

Differently said by Glăveanu (2018), **awe** can support a continuous engagement in “‘as if’, ‘what if’ and ‘if only’ thinking processes” (p. 519), to remind us of our nature which transcends the here and now and could aspire to more, to the yet impossible but, maybe, possible.

Cognitive Versatility

Leonie Baldacchino

The Edward de Bono Institute for Creative Thinking and Innovation, University of Malta, Msida, Malta

Abstract

According to dual-process theories of cognition, human beings process information by means of two independent but interactive types of cognitive processes, namely: Type 1, which is rapid, non-conscious, and automatic, and produces intuition; and Type 2, which is slower, conscious, and controlled, and leads to analysis (Evans and Stanovich 2013). A key premise of dual-process theories is that Type 1 and Type 2 processes operate independently from and in parallel with each other, and may therefore co-occur at different levels. This has given rise to the notion of cognitive versatility, which refers to the extensive use of both intuition and analysis, together with the ability to switch between them as needed (Hodgkinson and Clarke 2007). This entry begins by outlining the evolution of research on human cognition and cognitive versatility, followed by an overview of the key features of intuition, analysis, and cognitive versatility including the main contextual

factors that are likely to shape their deployment. It concludes with suggestions on how these cognitive processes may lead to the discernment of possibilities and the estimation of probabilities.

Introduction

According to dual-process theories of cognition, human beings process information by means of two independent but interactive types of cognitive processes, namely: Type 1, which is rapid, non-conscious, and automatic; and Type 2, which is slower, conscious, and controlled (Epstein 2003, 2010; Evans and Stanovich 2013). Type 1 encompasses various non-conscious cognitive processes, such as [heuristics](#) (mental shortcuts or rules of thumb: Gigerenzer 2008), ► [insight](#) (seeing the solution to a problem after a period of effortful reflection and/or non-conscious incubation: Sadler-Smith and Shefy 2004), and intuition (gut feelings, or “‘knowing’ without knowing why”: Hodgkinson et al. 2009, p. 279), while Type 2 incorporates a number of conscious cognitive processes, including critical thinking (objective

evaluation of an issue: Browne and Keeley 2014), and rational analysis (Evans and Stanovich 2013).

A key premise of dual-process theories is that Type 1 and Type 2 processes operate independently from, yet in parallel with each other. Notably, the two processing types are not in competition with each other, which implies that an increase in one does not take place at the expense of the other. In effect, Type 1 and Type 2 processes may co-occur at different levels, with such levels depending on contextual factors and individual differences. This has given rise to the notion of cognitive versatility, which refers to the extensive use of both intuition and analysis together with the ability to switch between them as needed, and which has been conceptualized as a cognitive style (personality trait / dispositional preference or inclination: Hodgkinson and Clarke 2007) as well as a cognitive strategy (actual use or processing in a given situation: Baldacchino 2013; Baldacchino et al. 2022).

This entry begins by outlining the evolution of research on human cognition and cognitive versatility, followed by an overview of the key features of intuition, analysis, and cognitive versatility including the main contextual factors that are likely to shape their deployment. It concludes with suggestions on how these cognitive processes may lead to the discernment of possibilities and the estimation of probabilities.

Evolution of Research on Cognition and Cognitive Versatility

Research on the evolution of human cognition indicates that the regions of the brain that give rise to intuition and other Type 1 processes evolved much earlier than those that generate analysis and other Type 2 processes (Evans and Stanovich 2013). Similarly, intuition was held in high esteem among laypersons long before analysis, with ancient societies hailing the former as “the most valuable kind of knowledge, . . . messages from the gods or evidence of . . . exceptional powers” (Noddings and Shore 1998, p. 4). The same cannot be said, however,

about research interest in intuition, because its spiritual and mystical connotations inhibited the scholarly community from attempting to study it scientifically, and led to a belief among researchers that intuition is an inferior cognitive process to rational analysis (Hodgkinson et al. 2008).

Consequently, cognitive theory was dominated until the 1970s by the notion of the “rational economic man” – or *homo economicus* – which posited that humans are rational beings who are capable of making decisions purely on the basis of conscious processes (Gibcus et al. 2008), and that intuition negatively influences cognition as it leads to irrational choices and behaviors (Peters et al. 2006). Over time, however, it became clear that it is not possible for humans to be entirely rational, as there are always limitations to the ability to engage in analytical processing. Rationality began to be viewed as “bounded” (Simon 2000) by constraints such as the availability of time and information. Furthermore, it became increasingly evident that nonconscious processes are often as pervasive as conscious ones in decision-making and behavior, and that research was required to shed light on the (nonconscious) processes which were at the time poorly understood (see chapter ► “Unconscious in Psychology”).

As a result, scholars gradually refocused their research from “cold” rational analysis to “hot” emotionally-charged processes including intuition (Böhm and Brun 2008; Peters et al. 2006). Indeed, as though in a bid to compensate for its neglect in research over the years, many studies focused on intuition to the exclusion of analysis. However, dual-process theories hold that intuition should not be studied in isolation but alongside analysis (Epstein 2003). The notion of cognitive versatility, which was proposed by Hodgkinson and Clarke (2007), is aligned with such views. So far it has received scant scholarly attention, but the few studies that have investigated cognitive versatility (Aggarwal and Molinaro 2013; Aggarwal et al. 2019; Baldacchino et al. 2022) indicate that it may be more effective than a dominant use of just one type of processing.

A Closer Look at Intuition, Analysis and Cognitive Versatility

Intuition is commonly referred to as gut feeling, and sometimes also as a sixth sense, that leads to “knowing” but without the ability to explain how or why that knowledge was attained (Hogarth 2001). The body of literature on intuition has led to various definitions and to the identification of a number of key features of this mode of processing. One of the most widely adopted definitions of intuition is as “affectively-charged judgments that arise through rapid, nonconscious, and holistic associations” (Dane and Pratt 2007, p. 40). This definition consolidates three elements of intuition that are found in many earlier definitions, namely that: (1) it is accompanied by affect, such as feelings of certitude or trepidation; (2) it occurs automatically and rapidly; (3) and it entails a pattern-matching process, often involving disparate pieces of information, which form into a coherent picture (Blume and Covin 2011). In addition to the above, Baldacchino et al. (2015) note that intuition is frequently associated with domain-specific experience, and they, therefore, suggest that this is a fourth key feature of intuition.

Due to the above features, intuition is more prevalent and effective than analysis in situations that are characterized by novelty, uncertainty, complexity, volatility, and time pressure, as well as in unstructured tasks that lack rules, guidelines, or information. In contrast, analysis, which may be defined as “the process of trying to understand a problem by breaking it down into its components and then performing logical and/or mathematical operations” (Klein 2004, p. 74), is predominant and more appropriate in stable contexts with sufficient, reliable information, clear rules and guidelines, and adequate amounts of time (Brigham et al. 2007; Burke and Miller 1999; Covin et al. 2001; Elbanna et al. 2010; Khatri and Ng 2000). Also in contrast with intuition, analysis (1) is not accompanied by affect, (2) is conscious, deliberate, and slow, (3) involves reasoning that is logical and linear, and (4) does not require domain-specific experience, such that novices are no less capable or likely than experts to engage in analytical processing.

As outlined above, dual-process theories hold that intuition and analysis may occur together, and the notion of cognitive versatility was introduced to refer to their abundant concurrent deployment. More specifically, Hodgkinson and Clarke (2007) proposed a four-quadrant framework, with intuition and analysis on perpendicular axes, and suggested that individuals may be classified into one of the four quadrants depending on the extent to which they engage in intuitive and/or analytical processing. They defined individuals who engage in high levels of analysis and low levels of intuition as “detail conscious,” those who engage in high levels of intuition and low levels of analysis as “big picture conscious,” those who do not engage in high levels of either type of processing as “non-discerning,” and those who “possess in equal abundance the inclination to attend to analytic detail *and* cut through that detail,” together with an ability “to switch more readily between analytic and intuitive processing” (p. 247) as “cognitively versatile.”

Hodgkinson and Clarke’s (2007) framework referred to cognitive style, which represents an individual’s dispositional preference for intuition or analysis, but more recent work (Baldacchino 2013; Baldacchino et al. 2022) adopted it to study cognitive strategy, which refers to the actual use of intuition and analysis in particular situations (Hodgkinson and Clarke 2007). Cognitive strategy may be shaped by cognitive style as well as by the nature of the task at hand, such as the amount of information and time available (Baldacchino 2019).

Although cognitive style (as a personality trait) is relatively stable, individuals who are not naturally cognitively versatile may still learn to overcome their dispositional preference for either intuition or analysis in order to become more cognitively versatile and employ the cognitive strategy (i.e., process/es) that is most appropriate in a given situation (Baldacchino 2019). To illustrate this point, one may consider ambidexterity as a metaphor for cognitive versatility: Although most people are either right-handed or left-handed and would prefer to carry out most actions using their dominant hand, they are able to use their non-dominant hand for a wide variety of tasks,

particularly (but not exclusively) those that require the use of both hands, such as driving a manual transmission automobile or using a fork and knife at the table. Moreover, although challenging, it is possible to use the non-dominant hand to perform actions that are normally done with the dominant hand, such as if the task context changes (e.g., if one is accustomed to right-hand drive cars and is required to switch to a left-hand drive one), or in the case of an injury to the dominant hand.

Cognitive Strategy, Possibility, and Probability

In simple terms, possibility refers to a chance that something may occur, that is, whether something could happen or not, whereas probability refers to the likelihood that it will occur, that is, the level of possibility that something shall happen (Cambridge Dictionary 2021a, b). The above-mentioned properties of intuition and analysis, together with the extant literature on cognitive versatility, suggest that these cognitive processes, styles, and strategies may play different roles in the discernment of possibilities and estimation of probabilities. To the extent that entrepreneurial opportunities may be defined as “the possibility to do things both differently from and better than how they are being done at the moment” (Wickham 2006, p. 236), and that opportunity exploitation decisions entail an (implicit or explicit) appraisal of their likelihood of success, the following research in the ► [entrepreneurship](#) domain may be drawn upon to support the above claim: Intuition and cognitive versatility have been found to be positively associated with opportunity identification (Baldacchino 2013; Baldacchino et al. 2013, 2014), while intuition and analysis were both found to be involved (in different ways) in opportunity exploitation decisions (Baldacchino and Boffa 2021).

Adopting Hodgkinson and Clarke’s (2007) terminology and a cognitive strategy lens, it could be argued that detail-conscious, big picture conscious, and cognitively versatile strategies would be more or less appropriate for thinking about

possibilities and probabilities depending on the nature of the task, along the lines described in the previous section (above) with respect to situational factors that would warrant intuition and/or analysis. Two key factors are the availability of information and time, as suggested below.

Where both information and time are abundant, engaging in slow, deliberate analysis of the information would enable a conscious generation of possibilities, together with an estimation of their probability using logical reasoning and mathematical formulae. Hence, when there is plenty of data to analyze and sufficient time to do so, a detail-conscious strategy would likely be appropriate.

Where information is abundant but time is limited, it would not be possible to engage in slow, deliberate analysis of the information. In such cases, intuition would enable a rapid visualization of possibilities, as well as a gut feeling about the probability or likelihood that they shall occur. Thus, when data is available but there is no time to analyze it, a big picture conscious strategy would likely be appropriate.

On the other hand, where information is limited but there are no time constraints, both intuition and analysis may come into play. Intuition could help fill in the gaps (Crossan et al. 1999) in the limited information to enable a visualization of possibilities, and could generate instant gut feelings regarding their probability. Given the availability of time, the analytical system could also be activated to analyze whatever information is present to consciously generate possibilities, which could then be subjected to an analytical estimation of their probability. The intuitively generated possibilities and probabilities could also be subjected to analysis, if time permits. Thus, when data is limited but time is not restricted, a cognitively versatile strategy would likely be appropriate.

When both information and time are limited, neither intuition nor analysis is likely to be activated. There could still be guesses about possibilities and probabilities, but such a cognitive strategy would be non-discerning as it would not be based on intuitive or analytical processing.

The above four conditions are mapped out on an adaptation of Hodgkinson and Clarke’s (2007)

Cognitive Versatility,

Fig. 1 Cognitive styles/strategies in relation to possibilities and probabilities (Adapted from Hodgkinson and Clarke 2007, p. 246)

framework in Fig. 1 below, in which the intuition and analysis axes are replaced by time and information. However, research is required to explore these proposed relationships.

Summary/Conclusion

As stated by Glaveanu (2018), “most of the times we think about the possible what we actually consider are possible futures” (p. 524). This entry has suggested that such considerations are likely to stem from both intuition and analysis, as what is ultimately enacted depends on individuals’ appraisal of situations, which in turn may involve intuitive and/or analytical processing, depending on the nature of the task/situation, and individual differences. Cognitive versatility is therefore the most effective style and strategy for thinking about possibilities and probabilities, as it enables individuals to make the best use of both intuition and analysis.

Coincidence

Bernard D. Beitman

Department of Psychiatry and Neurobehavioral Sciences, University of Virginia, Charlottesville, VA, USA

Keywords

Mind · Object · Meaningful coincidence · Synchronicity Carl Jung · Serendipity, Horace Walpole · Simulpathity, probability, random, personal agency, God · Complexity · Chaos, quantum, fractals

Definitions

A coincidence is a remarkable coming together of two or more incidents without an obvious causal connection between them (Beitman 2021). The word coincidence attracts two kinds of adjectives. One group implies no cause. These include: *coincidental*, *mere*, *only*, *pure*, *true*, *sheer*, and *just*. The other group implies that there might be a cause: *meaningful*, *remarkable*, and *amazing*. Throughout human existence the mystery of coincidences with the possibility of discoverable causes has fueled human curiosity. Coincidences can offer clues to how reality works (Johansen and Osman 2015) because they are hints of explanations not yet considered.

The nineteenth-century philologist H.E. Shepherd traced the origins of the words *coincide* and *coincidence*. He suggests that they probably began in Medieval Latin and then passed into the vocabulary of scholarly English writers during the first half of the seventeenth century, before probably being taken up by mathematicians during the great revival of mathematical study at that time in England. The words seemed to come into English through philosophy, having been translated from Roger Bacon's Latin or from the Latin of some other philosophical writer (Shepherd 1880).

The word *coincidence* became a household word in American English following the

simultaneous deaths of Thomas Jefferson and John Adams on July 4, 1826. The pair died exactly 50 years after each had signed the United States Declaration of Independence (Shepherd 1880). They died in different places, Jefferson in Charlottesville, Virginia and Adams in Quincy, Massachusetts. The US president at that time was Adams's son John Quincy who called the coincidence of their deaths on the nation's anniversary "visible and palpable remarks of Divine Favor" (Meacham 2012, p. 496).

Three primary categories of meaningful coincidences. Meaningful coincidences are characterized by some degree of similarity between or among the events. In the rest of this entry, the word coincidence is a shortened version of meaningful coincidence. The three primary categories of coincidences include: synchronicity, serendipity, and simulpathity.

Synchronicity: Carl Jung was doing psychotherapy with a woman who was resisting his attempts to help her change. One day she described a dream about a golden scarab. Jung then heard a tapping sound at the window. He got up, opened the window, and found a scarab-like beetle. "Here is your scarab," he said to her. The coincidence startled her into the direction of change (Jung 2010). This story has become best known example of synchronicity.

Jung (2010) stimulated imagination about meaningful coincidences with his ideas about synchronicity as an acausal connecting principle. Acausal connections involve mechanisms different from cause leading to effect. He was influenced by Chinese thought, especially the I Ching; medieval mysticism; the parapsychological research of J.B. Rhine (1947); and the theory of seriality as proposed by Viennese biologist Paul Kammerer (Townley and Schmidt 1994).

Jung invented this term, which means falling together in time, to explain meaningful coincidences. Synchronicity, as an acausal connecting principle, suggests that the shared meaning between two low probability events had something to do with explaining why they happened. The word has become synonymous with

meaningful coincidences. Jung's descriptive definition of the meaningful coincidences explained by the synchronicity principle includes two different aspects – psi-based coincidences (telepathy, clairvoyance, and precognition) and coincidences that facilitate individuation, the process of spiritual and psychological development (Jung 1973). The famous scarab story described in the next section represents the individuation form.

Serendipity: These are happy accidents. In 1921 microbiologist Alexander Fleming noticed that his accidental nasal drippings on the bacteria growing in a Petri dish in his lab created a halo of inhibition around the bacterial colony. In 1929 he noticed the same halo of inhibition in another Petri dish caused by the ooze from penicillin mold that had accidentally landed on the dish from another lab while he was on vacation. Through a series of further coincidences, that “mold juice” was manufactured in huge quantities to help save the lives of soldiers and others during World War II (Merton and Barber 2004).

Horace Walpole, a member of the British House of Commons in the eighteenth century, recognized in himself a talent for finding what he needed just when he needed it. Walpole first coined the term serendipity in a letter to his friend and distant cousin Horace Mann, the British minister in Florence, Italy, on January 28, 1754 (Merton and Barber 2004).

Walpole based the word on a fairy tale entitled “The Travels and Adventures of Three Princes of Serendip.” Serendip is an ancient name for the island nation Sri Lanka off India's southern coast. The king of the fable recognized that education requires more than learning from books, so he sent his sons out of the country to broaden their experience. Throughout the story, the clever princes carefully observed their surroundings and then used their knowledge in ways that saved them from danger and death (Merton and Barber 2004).

Serendipity relies on the intersection wisdom and chance to accidentally find something of interest or value. The intentions behind the activity taking place at the time of the unexpected observation or event are only indirectly related

to the outcome (Copeland 2019). There are two variations: (1) looking for something and finding it in an unexpected way and (2) looking for something and finding something entirely different and very useful. Fleming's discovery of penicillin, described in the next section, is an example of looking for something and finding it in an unexpected way.

Seriality: The phenomenon of seriality differs from serendipity and synchronicity in that it is a series of events in the objective world that the mind takes note of and remembers. Unlike the others, there is not necessarily a special subjective element. The series of events could theoretically be verified by anyone.

No one has perhaps described strings of similar events more thoroughly than Austrian biologist Paul Kammerer. He spent hours sitting on benches in various public parks, noting the people who passed by, classifying them by sex, age, dress, whether they carried umbrellas or parcels, and so on. He did the same during the long train rides from his home to his office in Vienna.

Kammerer defined “seriality” as “a recurrence of the same or similar things or events in time and space” that “are not connected by the same acting cause.” (This statement is a precursor of Jung's synchronicity principle.) However, Kammerer viewed these repetitions as simply natural phenomena.

In his 1919 book *Das Gesetz Der Serie* (The Law of Series), Kammerer outlined these laws and provided a broad set of classifications of serial types and qualities. This work on seriality helped Jung develop his concept of synchronicity. Afterwards Jung used a definition for synchronicity that was similar to Kammerer's definition of seriality. But Kammerer attributed the confluence of events to influences he thought were within the realm of known science (Kammerer 1919), while Jung relied on explanations outside known causal principles. Jung emphasized personal meaning, while Kammerer did not. Nevertheless, a series of improbable parallel events can seem quite meaningful. Meaningful series may take the form of a repeated phrase, seeing the same person in different contexts, or references to the same movie or book.

Simulpathity: At 11 pm on February 26, 1973, I was standing over the sink in a San Francisco Victorian house kitchen choking uncontrollably. I had never choked like that before and have not since. The next day, my brother told me that my father was choking and dying on his own blood at 2 am in Delaware on the east coast, the same time, 3000 miles away, I was choking in San Francisco. To bring the simultaneous choking into yet sharper perspective, my father died on February 27th which is my birthday (Beitman 2016b).

I coined this term to signify emotional/physical and usually subconscious empathy at a distance. The two people are not in the same place. One person feels some form of suffering of the other person. Only later is the simultaneity of the distress recognized (Beitman 2016b).

The Anatomy of a Meaningful Coincidence

Each coincidence has three major features: timeliness, similarity, and improbability. In this discussion, the word *coincidence* implies *meaningful coincidence* (Beitman 2022).

The time span between incidents can vary from a few seconds to years. The scarab and the choking involved small time intervals. Fleming and the discovery of penicillin took 8 years to manifest.

Some incident pairs are exact matches. More often they approximate each other. The scarab in the dream was not exactly the same as the scarab-like beetle that Jung captured and placed in front of the dreamer. Fleming's halos of inhibition were probably more similar than identical to each other. And I was not choking on my own blood as my father was.

A coincidence is an unlikely event with a probability that is currently difficult to calculate. While there is debate about how well people judge coincidence probability (Diaconis and Mosteller 1989; Johansen and Osman 2015), the lower the estimated probability, the less likely the coincidence can be explained conventionally.

Mind and Object

Coincidences are formed from two kinds of incidents: **Mind** and **Object**. **Mind** incidents are thoughts, feelings, sensations, and images. No one else can observe them. **Object** incidents are things and events that anyone could observe.

Mind-Object is currently the most common coincidence form. The coincider (the person experiencing the coincidence) thinks, imagines, or feels something that is paralleled in a thing or event outside of their mind. The Object in Mind-Object takes several forms; it can be another person, information, a thing, a mirrored psychological conflict, or a predicted future event that comes true. A common example is thinking of someone you have not thought of for a long time and that person unexpectedly contacts you (Coleman and Beitman 2009).

Mind-Mind refers to thoughts, feelings, or images that two people share and that can only be known when one reports them to the other or to an intermediary. They include telepathy and simulpathity events. Twins, especially identical twins, seem to experience the highest frequency of mind-mind coincidences. They show strong psychological as well as strong physical parallels both at a distance and in the same place (Playfair 2012). In addition to twins, other pairs of people who share a strong emotional bond, including mother-child and close friends, also are likely to experience Mind-Mind coincidences (Stevenson 1970).

Object-Object coincidences involve a series of two or more things, symbols, numbers, words, and other visible or auditory forms, each of which is similar to the other(s) in the series. These are public events that anyone present can witness. A prominent example is the simultaneous deaths of Thomas Jefferson and John Adams, both on July 4, 1826, 50 years after each had signed the declaration of independence.

Explanations

The most popular explanation for coincidences is that God or "the Universe" is responsible (e.g.,

Rushnell 2006). There is no arguing against the First Cause since, to people of strong religious faith, God brought everything into existence and continues to do so including every coincidence. The second most popular explanation for coincidences is randomness, that there is a probability that any event, however improbable, can happen (e.g., Hand 2015). The notion of Personal Agency, that the person or people involved contribute to the creation of the coincidence, is a third often neglected explanation. Also neglected is the recognition that multiple forces help to produce coincidences. Indeed, most attempts to explain a coincidence assume that one explanation works for all coincidences.

Probability/Random

All coincidences have a probability of happening. This characteristic, however, does not serve as a full explanation. By analogy, each human being has a mother. However, mothering cannot explain all human behavior. For both coincidences and mothering other variables contribute to explanations.

Statisticians claim that in large populations any strange thing can happen – they call this the Law of Very Large Numbers (Hand 2015). The Law of Very Large Numbers has not been proven the way the law of gravity has. Nor has it been proven in the way that mathematicians *prove* certain statements. The similar sounding Law of Large Numbers has been proven both mathematically and experimentally. The differences between the two laws illustrate the problems with the Law of Very Large Numbers. Indeed some writers confuse the two by saying The Law of Large Numbers when they actually mean the Law of Very Large Numbers. The Law of Large numbers states that “As a sample size grows, its mean gets closer to the average of the whole population” (Dinov et al. 2017). For example, the more times a coin is flipped, the closer the average of heads and tails comes to the theoretical average of $\frac{1}{2}$ or 50% each. Or, the more times a true die is rolled, the closer the appearance of each number comes to $\frac{1}{6}$ or 16 2/3%. It is a law like the law of gravity by

being a fundamental aspect of our reality. On the other hand, the Law of Very Large Numbers has not been proven experimentally and cannot be proven through a mathematical proof. Instead this “law” is a belief. Stating the belief that in large populations any strange thing can happen as a “law” obscures the subjective nature of the claim. The Law of Very Large Numbers resembles the laws made by governments rather than those lawful regularities discovered by science.

Statisticians recommend calculating probabilities of coincidences by multiplying the base rates of each incident. A base rate is the frequency at which an incident occurs. If one person thinks of another person and that person texts her, the base rates could be calculated by knowing (1) how often the first person thinks of the other person and (2) how frequently the other person texts the first person. But this calculation ignores the time span between the thought and the text. The closer in time of this coincidence, the lower the probability. From the simple base rate calculation a coincidence occurring 1 min apart and one occurring a week apart would have the same probability. Statisticians do not include time span in their calculations of the probability (Hand 2015). But time span does influence probability and should be included in most (but not all) probability calculations. The discovery of penicillin, for example, took 8 years between the first and second incident. Degree of similarity between and among the events should also figure into the probability. The greater the similarity between events, the lower the probability. How to include time span and similarity in probability calculations has yet to be clarified.

Because there is no accepted scientific theory other than randomness to explain how coincidences happen, conventional scientists reject further study of coincidences, except to criticize other explanations (Lewis 2020).

Personal Agency

Some minds are inclined toward seeing coincidences and some are not; in other words *bias*. For those who are predisposed, the *recency/availability*

bias allows them to use recent events to match a current event. The *hindsight bias* can encourage an excessive retrospective increase in the significance of a coincidence (Hand 2014). However, the hindsight bias also is pragmatically useful. Serendipitous discoveries in science are recognized through hindsight when their value becomes evident. The value of penicillin was not recognized until many years after it was discovered (Copeland 2016).

Once beliefs are established, minds are reluctant to let go of them. Instead they seek information that confirms their correctness – *confirmation bias*. Since similarity between two events is fundamental to coincidences, the desire to confirm this similarity can excessively stretch the pattern of one event to match the pattern of another event to confirm the established belief.

Self-defined spiritual and religious people see more coincidences as do *self-referential* people who tend to see events around them as related to themselves. Others who are more likely to notice coincidence include those *seeking meaning in life* and people who are *highly intuitive* (Costin et al. 2011; Attig et al. 2011; Coleman and Beitman 2009). The Weird Coincidence Survey, which estimates personal coincidence sensitivity, was used to determine these characteristics (Coleman and Beitman 2009). (The Weird Coincidence Survey may be taken at Coincider.com.)

Situational Variables

Situational variables play key roles in the likelihood that coincidences will take place. These include need, life stressors, and high emotion (Beitman 2016b).

When in *need*, a person may consciously or unconsciously scan the environment for potential sources of help, increasing the potential connections between mental events and environmental events (Mind-Object coincidences) (Duggan 2020).

Life stressors involve the passing from one role to another, a change in mental or physical state, or the transition from one life stage to another one. They include weddings, deaths, births, job changes, sickness, and relationship changes. On

the scale of 1–100, death of a spouse ranks the highest at 100. A comprehensive list of life stressors is found in the Holmes-Rahe Stress Inventory (Noone 2017). Life stressors pull people out of their ordinarily structured lives which open up possibilities for new connections.

High emotion increases the mind's drive to make connections with other minds and objects in the environment. The high emotion can be positive or negative. But if the emotion is too strong, it can obscure recognizing potential coincidences (Allsop and Gray 2014).

Conventional Science

Recognized brain and mind capacities can explain some coincidences.

Ocular saccades. Not uncommonly, people report that when they glance at clocks the same number seems to show up in their line of sight. They may glance at wall clocks, car clocks, or computer screens and see 11:11 and wonder why they are seeing the same numbers. Ocular saccades are rapid, ballistic movements of the eyes that abruptly change the point of fixation. They range in amplitude from the small movements made while reading, for example, to the much larger movements made while gazing around a room (Purves et al. 2001). Through these eye movements a person may have subconsciously noticed that their timepiece is registering this number again so they looked. Since they did not recognize the number consciously, the series of time coincidences appears to have no obvious cause.

Similarly, *supersensitive hearing* may produce subconsciously tracked events that are matched with a conscious event leading to an unexpected coincidence. A caller into a radio show on which I was being interviewed told this story: Walking down a street, the man felt the impulse to rush ahead and grab two small children playing under a tree. Just as he swept them away, a large tree branch fell right where they were playing. The most likely explanation for his action is that he heard the cracking of the branch that was about to fall.

Concordance refers to people who know each other well and who are then likely to be coincidentally thinking the same things at the same time and finishing each other's sentences (Blackmore and Chamberlain 1993). It appears to be telepathy but could be strong familiarity.

Resolving psychological conflicts. Outside of their awareness, people are able to create coincidences to resolve inner conflicts (Williams 2015). One of the participants in my Weird Coincidence Survey research at the University of Missouri-Columbia (Coleman and Beitman 2009) reported this story: "After I was widowed, I began dating again. I was concerned with what my late husband would think. One day while visiting his grave, I accidentally cut my ring finger with some grass clippers. I had to go to the Emergency Department, where they removed my wedding ring. My boyfriend and I took it as a sort of sign that it was okay to proceed in our relationship." To an outside observer the coincidence can be explained by the actions of the coincider. By attributing the cause to mystery, personal responsibility is removed, which fosters the feeling of being guided and cared for.

Group contributions. Coincidences often involve other people, yet their contributions are regularly not recognized. No scientific discovery, for example, occurs in isolation from the scientific community. The agency of an individual within that community (whether at the time or even posthumously) is what determines how and whether their observations are taken up into a process of discovery by that community. Serendipitous discoveries in science cannot be fully described in terms of a single individual at a particular time or place. Rather, facts about the context and culture determine the perceived value of the discovery (Copeland 2015).

Emerging Scientific Theories

Conventional science can explain a limited number of coincidences. New theories are emerging that have the potential to widen our range of understanding of how coincidences happen.

Complexity and Chaos Theories

Emergent properties characterize complex and chaotic systems. An emergent property can be described as novel in the sense that it cannot be reduced to the properties that exist in the underlying process or context from which it arose (Clayton 2006). A popular example is the idea that consciousness "emerges" from the neural networks of the brain.

Jungian Psychologist Joe Cambray (2011) suggests that complexity theory could add to further understanding of synchronicity theory. Cambray believes the fluid state between order and disorder that characterizes complex system is filled with creative potential, yet is also potentially dangerous. Too much chaos may lead to psychotic thinking. Structure grounds emerging creativity. Too much structure leads to rigidity since emergence requires flexibility in a system to reconfigure. As Robert Frost wrote "You have freedom when you're easy in your harness." To Cambray this fluid state also gives birth to synchronicities. Complex systems can exhibit self-organization – the system spontaneously orders itself without external control. The emergent property of self-organization may result in synchronicity (Cambray 2002).

Philosopher Samantha Copeland (2019) suggests that the serendipity in scientific discovery also emerges from the fluid state between structure of wisdom, skill, and knowledge and the unpredictability of chance, luck, and randomness.

Psychologist Robert Sacco (2018) investigates the relationship between fractal symmetry and synchronicity. He uses birthdate as the temporal location to predict fractal correlations later in life. While exact fractals are built by repeating a pattern at different sizes, synchronicities are related to "statistical" fractals that introduce randomness into their construction so that the elements of the coincidence are not exact repetitions. These repetitions can then be paired to form coincidences since individual fractals are similar at different levels of scale. Sacco proposes that because chaos can create fractals, chaos theory can help explain some synchronicities.

Chaotic systems can produce fractals which are selfsame (the same as previous) repeating patterns that could become Object-Object coincidences (Sacco 2020).

Complex and chaotic systems are nonlinear, dynamical systems.

A dynamical system is a system whose state (and variables) evolve over time, doing so according to some rule. How a system evolves over time depends both on this rule and on its initial conditions – that is, the system’s state at some initial time. Feeding this initial state into the rules generates a solution. . . which explains how the system will change over time; chaos is generated by feeding solutions back into the rule as a new initial condition. In this way, it is possible to say what state the system will be in at a particular time in the future. (Rickles et al. 2007).

A small change in some variable can result in a large change in the system yielding either a predictable outcome or a potentially random outcome making outcomes sometimes difficult to predict (Rickles et al. 2007). Building on the unpredictable factor in deciding a career, some career counselors encourage their clients to rely on serendipity to advance their careers (Pryor and Bright 2007).

Chaotic systems generate intricate behavior from the repeated application of a simple, mathematical rule. Complex systems generate intricate behavior from simple interactions between large numbers of subunits that feedback into the behavior of the parts.

The link between emergent properties of complexity theory and the fractals of chaos theory may have to do with the relation between quantum theory and nonlinear dynamical systems (Sacco 2020).

Potential Scientific Explanations

Although stubbornly rejected by conventional science, psi offers partial explanations for a subset of coincidences. The observations from the micro-worlds of quantum mechanics are speculated to take place in the macro-world of ordinary human living. That our minds are embedded in a Greater Consciousness emerges as another speculative explanation for some coincidences.

Psi

Most prominent among potential explanations that are not currently accepted by science involve psi or ESP processes since many coincidences can be easily ascribed to telepathy, clairvoyance, or precognition. Indeed Jung’s classification of meaningful coincidences included examples of each of these. Research into telepathy, clairvoyance, and precognition has yielded numerous case reports and large numbers of well-designed laboratory research studies. Parapsychology research, which includes psi, drew a strong, positive review in *The American Psychologist*, a prominent American science journal (Cardena 2018). Psi abilities have been catalogued across the world’s religions, each tradition having stories about people with extraordinary abilities (Irvine 2008). But no one knows how psi works, so many authors have criticized psi research (Shermer 2003; Hand 2014) and will continue to do so until mechanisms to explain telepathy, clairvoyance, and precognition are established.

One possible partial mechanism is Psi Mediated Instrumental Response (PMIR), first proposed by St. John’s University psychologist Rex Stanford. Individuals may unconsciously obtain extrasensory knowledge of events relevant to their personal needs and use this knowledge to modify their behavior in a way that can be helpful (instrumental) in satisfying those needs. Of the dozen items on the Weird Coincidence Survey, this response was in the top four: “I advance in my work/career/education by being in the right place at the right time.” Somehow people get where they need to be at the right time. A substantial body of research by Stanford supports the existence of PMIR (Stanford and Stio 1976; Stanford et al. 1975; Palmer 1997; Duggan 2020).

I have given the Stanford acronym PMIR a friendlier face; I call it Human GPS – the ability to get where you need to be without knowing how to get there. Being in the right place at the right time happens often but subconsciously. The mere act of randomly choosing a seat in a movie theater, arriving late for an appointment, following an intuitive nudge, or getting lost in a car can yield serendipitous results.

Some meaningful coincidences seem to escape the psi explanation net. What are we to make of them? The ones that seem unexplainable beckon curiosity and investigation. Their mystery someday may be elucidated.

Skeptic Michael Shermer makes his living debunking ideas like psi (Shermer 2003) yet he was confronted with a meaningful coincidence that he could not explain. As he reported in *Scientific American*, he was about to be married in his home when a long silent radio belonging to the deceased grandfather of his bride began playing romantic songs. She had wanted her dearly beloved grandfather to be present and to her the radio brought him to her. After the ceremony was completed, the radio went silent once again and years later was silent still (Shermer 2014). Shermer rejects the notion that this was a form of communication from her deceased grandfather; he also dismisses the possibility that his bride so wanted her grandfather to be there that she unconsciously caused the radio to turn on. Both these are parapsychologist explanations. Shermer prefers a “natural science” explanation that suggests the grandfather “exists in a 5th dimensional tesseract and is using gravitational waves to turn on his old radio for his granddaughter” (Shermer 2018). Shermer’s explanation may be even more speculative than any parapsychological explanation.

Quantum Mechanics

The application of quantum mechanics seems to promise help in solving some of the explanatory mysteries of coincidences.

In quantum mechanics, the activity of electrons, photons, and smaller particles has catapulted two captivating ideas into common awareness – quantum entanglement and the collapse of the wave function.

For *quantum entanglement* to occur two particles like electrons or photons must be so closely linked that one cannot be defined without reference to the other. Then a change in a characteristic of one particle is instantly paralleled by an equal and opposite change in the other particle, no matter what the distance between them (Orzel 2017). Entanglement has become a metaphor for telepathy and simlupathity occurring between two

“entangled” individuals (Beitman 2016b). Whether this is more than a metaphor remains to be seen. Physicists are bringing entanglement to large systems, including clouds of atoms, quantum drums, wires, and etched silicon chips entangling large and larger systems (Ornes 2019). Where the micro- to macro-limit exists is yet to be determined.

Collapse of the wave function refers to the particle-wave duality – the particle and the wave complement each other as two aspects of what may be the same thing. An unmeasured wave of a photon or electron can be in many different possible particle states. When the wave is measured (observed), one of the possible particle states becomes real. At the macro-level, by a huge stretch of the imagination, a strong need could create coincidences by acting like the observation of a particle so that the need “collapses” a band of possibilities, analogous to collapsing the wave of possibilities into a particle state, from the person’s reality into the desired state. The application of quantum particle activities to the macro human world needs much further substantiation.

Greater Mind

Jung theorized that mind and object each emerges from an undifferentiated whole, the *unus mundus*, which somehow “contains” archetypes which are enduring patterns of human thought and action. Archetypes are somehow constellated (activated) which then brings the mental together with the physical, thereby creating Mind-Object coincidences (Jung 1977). Quantum physicist Niels Bohr stated that “materialism and spiritualism [that is, the physical and the psychic] . . . are two aspects of the same thing” (Honner 1988). Physicist David Bohm (1980) argued that the physical world that we see (the “explicate order”) first exists as a potentiality in an unseen, undivided whole (the “implicate order”). When something appears in the material world, it has unfolded from the implicate order, and when it disappears from the material world, it enfolds back into the implicate order. Bohm and physicist F. David Peat have suggested that both mind and matter emerge from the implicate order, and are thus inseparable (Bohm 1980; Peat 1987, 2014). Kastrop (2019)

makes similar claims. Barušs and Mossbridge (2017) argue that synchronicities occur when structures within deep consciousness extrude into our ordinary waking state.

The sheer number of similar speculations by respected researchers about an implicate order suggests this might be a fruitful avenue of investigation.

Coincidence and the Possible

Coincidences encourage meta-positions vis-à-vis reality. By stimulating curiosity about personal meaning and possible explanations, coincidences activate the self-observer. The self-observer can connect emotions, intuition, thoughts, and images to events in the environment, including ideas in the minds of other people (Deikman 1982). To notice a coincidence usually involves simultaneously holding in mind two or more separate events. As they are being held in mind, the self-observer can examine their similarity, probability, emotional charge, and meaning.

From this meta-position, reality, experienced both subjectively and objectively, can continually be re-imagined. Since interpretation of coincidences relies on both intuition and rationality, these two relatively distinct information processing modes can come increasingly more able to function together.

Since explanations of coincidences often involve multiple influences, understanding coincidences requires practice in thinking simultaneously about multiple possibilities. At minimum, these multiple explanations include probability, brain function, personal agency, situational variables, and group influences, while also recognizing that the future holds explanations yet to be discovered and substantiated.

Because Mind-Object coincidences hint at closer connections between mental events and environmental events, coincidences challenge the standard assumption that mind is contained solely within the brain. As the reality of Mind-Mind coincidences becomes recognized, the implicit barriers between and among minds may possibly become less definitive. If two people are

thinking or feeling the something similar around the same time, their minds appear to be more closely connected that is conventionally considered. Thinking something and then having it happen is also a common coincidence form. Increasing evidence suggests that human minds may be emerging as nodes in Internet-mind connectivity. These connections go beyond programs that feed Internet users ideas in which they have expressed on-line interest (Beitman 2016a).

The Usefulness of Coincidences

The attractiveness of coincidences for exploring new frontiers is generated in part by their usefulness. Their usefulness calls attention to them. In the future people may increasingly and deliberately employ coincidences in a broader range of human activities than which they are currently being used.

Coincidences can be useful in most aspects of personal life: romance, family, friends, psychological change, sickness, jobs, and spirituality (Hopcke 1998; Beitman 2016b; Rawlette 2019). Classroom teachers can benefit from considering that their minds and the minds of their students may have parallel thoughts and feelings (Bache 2008).

Science and technology have advanced quietly on the wings of serendipity, often resulting in Nobel Prizes (Austin 2003; Van Andel 1994; Merton and Barber 2004; Meyers 2007). Should funders finally acknowledge the value of these happy accidents, the future will likely see exponential growth in practical new ideas stimulated by serendipity (Yaqub 2017).

Leadership in business organizations is beginning to benefit from synchronicity awareness and use (Jaworski 2011). Possibilities for expanded applications are being explored.

Coincidences can and do propel the plots of narrative fiction; many fairy tales, novels, movies, and plays turn on meaningful coincidences. No coincidence, no story (Dannenberg 2004; Browne 2019)! Recognition by readers and audiences of narrative coincidences, through coincidence film festivals for example, can sharpen the public mind to their ubiquity. The audience can be asked to spot the coincidence! Activities like these will

help to increase coincidence awareness in daily life.

Coincidences can reveal and expand latent personal powers. Currently controversial, psi may come to be recognized as part of the natural world (Cardena 2018). Related experiences including simulpathity (Stevenson 1970) and human GPS (Stanford and Stio 1976; Palmer 1997) have gained some research support. Discovering the mechanisms underlying these human abilities will be made increasingly possible as funding sources recognize their ordinariness. In the meantime, coincidences can provide personal validation of these observations.

Increased awareness and use of coincidences can have their downside. Synchronicities and serendipities are often presented as only positive. Like technological innovations, they can also be problematic.

They may be used to deceive someone or be fabricated to attract attention. They may trigger destructive actions. They may seem to promise an outcome that does not materialize. A high frequency of coincidences can be overwhelming. They also can be symptoms of psychosis. (For detailed examples, *Meaningful Coincidences: How and Why They Happen*, forthcoming.) The future will help to identify not only beneficial coincidences but also potentially harmful ones.

Summary

Coincidences have long served humanity as clues to predicting and controlling events. Meaningful coincidences are composed of two primary elements, Mind and Object, which create three coincidence forms: Mind-Object, Mind-Mind, and Object-Object. They can be useful in many aspects of human life on a personal level and also in science the arts and business leadership. Coincidences can also continue to serve as probes into the mysteries of life to expand our understanding of reality. They also exercise the mind by activating individual self-observers and by requiring the application of both intuition and rationality in their interpretation. In addition

their explanations require thinking simultaneously about multiple possibilities while also challenging the belief that mind is entirely separate from environment. The continued expansion of interest in coincidences will help to open human minds to yet unthought-of of possibilities.

Abstract

In this entry we suggest that a shared view of the possible has accompanied the development of successful creative collaboration both in modern time, in the historic past, and from the viewpoint of deep history. The concept of the possible in collaborative creativity is distributed, in rather than predicated on an individual, at times this possible is unknown by all until the moment it becomes actualized. The possible, when considered in this way, becomes a relational phenomenon existing in a shared future both inspiring collaboration and also inspired by it. This entry will start by drawing a distinction between creativity in groups and collaborative creativity before moving to examine how a distributed sense of the possible drives commonly collaborative ventures such as in music or science and how collaboration unfolds across multiple time scales. Finally, we will move to an aspect of creativity more rarely considered from a psychological perspective – that is how creativity appears in the archaeological record. The study of creativity should have great appeal to pre-historians: The remarkable creativity of our species appears to be one of the defining features that separates humans from the rest of the animal world, but an individualist view of creativity has stymied previous study. Our review of the current evidence suggests that the fundamental building blocks of the development of human creativity lie in demographic and

We would like to thank Frédéric Vallée-Tourangeau for his helpful comments on an earlier draft.

neural changes relating to social engagement. This points to the tantalizing suggestion that all creativity should be considered as collaborative.

Collaboration · Deep History · Distributed Creativity · Demography · Social intelligence · Extended Mind · Entanglement

What is indisputable [...] is the fact that humans live not only in the here and now but are capable of enriching and expanding their experience of the world by remembering the past, imagining the future, considering alternatives, anticipating problems and continuously engaging in ‘as if’; ‘what if’ and ‘if only’ thinking processes. The common denominator between these experiences is the capacity to go beyond the actual or the real and to explore the possible. (Glăveanu 2018, p. 1)

In this entry we suggest that a shared view of the possible has accompanied the development of successful creative collaboration both in modern time, in the historic past, and from the viewpoint of deep history. Conversely, collaborative creativity also expands and surpasses the boundaries of what is possible for an individual to conceive and to achieve. So for example, the improvisatory genius of a single individual such as, say, John Coltrane, can be best understood as emerging from several entangled factors: the material and collaborative conditions of the jazz music of his day, for example, the saxophone, bass and drums; the US economy; the changing language of jazz; the ethnic and social aspects of his time; and the social demographics and the possibilities of collaboration in his musical scene. Beyond these material necessities, his band’s ability to follow his innovative approaches to the language of jazz was also integral to his musical talent. Thus, while his individual qualities arguably drove the resultant product, a true understanding of creativity needs to also settle on a level of analysis which takes into account these factors.

Additionally, because the concept of the possible is distributed, in our view, rather than predicated on an individual, at times this possible is

unknown by all until the moment it becomes actualized. The possible, when considered in this way, becomes a relational phenomenon existing in a shared future both inspiring collaboration and also inspired by it.

This entry will start by drawing a distinction between creativity in groups and collaborative creativity before moving to examine how a distributed sense of the possible drives commonly collaborative ventures such as in music or science and how collaboration unfolds across multiple time scales. Finally, we will move to an aspect of creativity more rarely considered from a psychological perspective – that is how creativity appears in the archaeological record. The study of creativity should have great appeal to prehistorians; the remarkable creativity of our species appears to be one of the defining features that separates humans from the rest of the animal world. Our review of the current evidence suggests that the fundamental building blocks of the development of human creativity lie in demographic and neural changes relating to social engagement possibly pointing to the tantalizing suggestion that all creativity should be considered as collaborative.

Collaborative Creativity

There are two distinct strands when it comes to psychological research examining how we are creative in groups, which are perhaps more complementary than their supporters care to admit. However, each posits diametrically opposed views of the ontological locus of creativity and, importantly, the level of analysis necessary to unpick it. One views creativity as an essentially individual process and has as a research focus individual attributes which are reduced even so far as the firing of neurons associated with creativity (see Sawyer 2011 for a review). Others reject the idea such a closed system is reflective of true creativity, rather they suggest that creative processes and products arise from a combination of people, products, and moments (Glăveanu 2015; Montuori and Purser 1995; Ross and Vallée-Tourangeau 2018).

An understanding of these two viewpoints can elucidate the difference between collaborative

creativity and group creativity. This latter sees creativity as a linear, additive process preserving the boundaries of the individual as she works in a group. This research focus necessarily privileges both the individual as a unit of analysis and a quantitative methodology which often employs tasks such as the Alternative Uses Task to quantify creativity. Such an epistemological position pins the locus of creativity on the individual and casts group creativity as something that occurs when a measurable outcome is formed by the interaction of these individual creative units (Glăveanu 2011). The individual is the focus of attention rather than the group.

However, this research program, while elucidating some aspects of the creative process, does not reflect collaboration as documented across other naturally occurring domains. Those who assert collaborative creativity is distinct from group creativity suggest that some creative processes and products cannot be fully understood at the individual level of analysis and that group level analysis is necessary (Glăveanu 2011; Sawyer 2010). The level of analysis is not trivial here in understanding how we can unpick the creative process when it unfolds collaboratively. Collaboration is necessarily a group activity and, if we study collaborative creativity, then a model which reduces beyond the group level will lose much explanatory power.

Moran and John-Steiner (2004, p. 11) refer to collaboration as “an intricate blending of skills, temperaments, efforts and sometimes personalities to realise as shared vision of something new and useful.” Regarding collaboration as a naturally occurring relationship between two or more people often leads to changes in methodology with a focus on a qualitative, idiographic approach exploring how non-substitutable components interact. These components will almost certainly have different qualities to each other and thus products of collaboration as a complex system are perhaps best considered as truly emergent – that is irreducible to their constituent parts (Sawyer 2004).

Research into collaborative creativity approaches creativity as an in-between process with a final creative product that emerges from the combination and interaction of different,

complex actants. As a result, the product and process cannot be reduced to individual units of analysis. The focus of this entry will be on how such collaborations involve a creative product that is only possible as an emergent product of that collaboration. In this way, we fundamentally reject the idea that collaboration consists of a group of interchangeable actants, rather our notion of collaboration is that it is unique, occurs on multiple timelines, and is irreducible.

Collaborative Creativity and an Emergent and Distributed Possible

Improvisational Jazz

When the possible is distributed across different members of a group, then what is actualized is a shared vision which is often not available to the members of the group until the moment it comes into being. This is true for rehearsed and iterative group composition, but it finds its apex in improvisation where the product is ephemeral and explicitly interactional. For example, group jazz improvisation is an art form which simply cannot be understood in terms of individual, conscious cognitive processes and where what is possible is predicated on what occurs at the group level rather than individual contributions. Indeed, this form of group creativity is so explicitly collaborative that Seddon (2004) suggests it generates an “empathetic creativity,” that is, a creativity that is necessarily dependent on the presence of others.

In the domain of psychological research this art form is often used as a fundamental challenge to a reductionist notion of creativity (Kenny 2014; Sawyer 1992). This is not only because an analysis of the individual’s creative output would not capture the final product in a satisfactory manner, but also because it is impossible for the individuals in the group to know, let alone shape the creative process in its entirety (Sawyer 2010). In improvisational performance the social group is not only conceived of as influence but as co-creators. Again, the appropriate level of analysis is fundamentally important.

In addition, it is impossible to assess the creativity of such groups without an awareness of their

positioning in a temporal space where the collaboration is not only with the current members of the band but also with the musical tradition. For free form jazz is not as uncontrolled as might be first assumed, rather its novelty arises from the recombination of learned set pieces and is contingent on a shared thought and moment as well as a deep shared history. Thus when we are assessing the creativity of such a group, the traditional methods of assessing the product cannot work because it is necessarily ephemeral, so we must take into account the process, and the practice of music making; the “creative process and the resulting product are co-occurring” (Sawyer 1992, p. 253). For this type of collaborative creativity, there is no individual ownership of the final product and so the moment at which the possible is conceived is at the moment of actualization.

Scientific Collaboration

The distribution of the possible also arises in more concrete forms of creativity. Scientific innovation has always been collaborative – the first coauthored paper appeared in 1665 (Beaver and Rosen 1978) – but there has, however, been a significant increase in scientific collaborations with ambitious projects such as the Large Hadron Collider pooling resources in order to further scientific discovery and creativity in way that a single team cannot afford to do in terms of either financial or human resources. Coauthorship of scientific papers has been rising steadily both in terms of the numbers of authors and the number of countries from which those authors are drawn (Gazni et al. 2012). Technological changes have both facilitated this deeper level of collaboration and meant it is necessary as the technical skills needed to operate equipment require levels of expertise that cannot be found in a single individual. Thus, the shared possible here becomes a fractured product if only considered at the individual level. The possible here is greater than the sum of its parts.

Increased collaboration has a positive impact on productivity and the citation level of individual researchers, but it also has a wider impact than

this; it effectively increases the range of what is possible in scientific research. Beyond the pooling of financial resources, scientific collaboration allows creativity to develop in a nonlinear, iterative, and reciprocal manner. The benefits of scientific collaboration are not just realized by a brute force increase in numbers but also by encouraging and exploiting disciplinary diversity. Here what is possible is not determined by what is similar between collaborators but what is different and the possible arises in these complementary tensions. As we have seen above, what emerges is more than a linear, additive formula treating collaborators as interchangeable units. This transdisciplinarity is essential to capitalize on serendipitous discoveries (Rocca et al. 2019).

As collaboration occurs across disciplines, it encourages diverse groups of researchers to pool different areas of expertise to create something that would not be possible for one individual. This, in turn, allows individuals to become increasingly specialized within a team of other specialized individuals which they would not be able to do without offloading some skills to others (Ness and Riese 2015). This creates an iterative relationship between the individual and the group extending beyond an analysis of the scientist as an individual. Again, the possible cannot be understood at an individual level but emerges from the process of multiple, different individuals. Moreover, just as with a jazz ensemble this collaboration extends back in time as well: any discoveries are made through collaboration not only with those researchers currently on the project but also those who have already made the necessary advances.

Trust and Tension

Modern scientific collaborations require a high level of trust (Andersen 2016) and its increasing complexity supports specialist knowledge rather than a polymath. This requires relinquishing individual control. Trust is not a given and therefore, it also needs to be assessed in the context of the temporal developments of the relationship. Such trust can only develop over time and grows as the

relationship develops allowing for a steady widening of the boundaries of the possible.

This is also true for artistic collaboration. In a jazz ensemble, for example, band members cannot be simply exchanged for other equally talented members with the same outcome because music making in such groups is a dynamic and shifting mix of formal and informal approaches. While jazz players can be substituted the dynamic mix will result in a different final product. As is the case with the types of close creative collaborations outlined above, creative processes in this environment are informed by social processes as much as the act of creativity itself (Kenny 2014). Importantly, satisfactory improvisation in such groups does not happen spontaneously but rather arises from social interactions that act as backdrop to supply the level of trust necessary to work collaboratively (Kenny 2014; Seddon 2004). The creativity is enacted in the moment, but the collaborative ties are formed over time. In her ethnographic study of creative collaboration in a jazz ensemble, Kenny writes of a “sense of camaraderie” (p. 4) and a “shared history” (p. 5) and Seddon tells of two members of the band he studied who had attained a higher level of “sympathetic attunement” (p. 73) through spending time playing and travelling together. The piece of music then emerges from this mix of current work and shared history and cannot be understood simply as the addition of talents from interchangeable components in an easily generalizable model (Sawyer 2006).

Material Collaboration

The creative product is often constrained by the things around it. Just as the initial flurries of artistic creativity in our prehistoric ancestors were often constrained and used the surrounding natural features to shape their artistic output (Froese 2019), so materials can be considered key collaborators in the creative process to this day. In the same way as human collaborators serve to shape the final creative product, so materials exert an influence over the process.

That the materials used in artistic creativity influence the creative act and shape and constrain what can be done is a commonly reported phenomenon. Take, for example, the experience of working with clay. Paul March’s (2019) writings on this process reveal how the actual physical materials with which he works shapes the creative process with the delicate nature of porcelain contrasting with the more robust nature of stoneware:

The physicality of sculptural experience can be felt by comparing two different clays: stoneware and porcelain. Metaphorically speaking, stoneware is dynamic, generous and forgiving—confident in its plastic potential. Porcelain is intransigent and full of inertia. With porcelain, the act of creation and the outcome of the engagement with my hands take place within boundaries set by the clay’s limited elasticity and excessive friability. Sculpting with porcelain is a tense negotiation. (March 2019, p. 137)

The subtly different affordances of the material used intervene in the final artistic work similar to the way in which a human collaborator would. Again, the possibilities arise in the difference, in the “negotiation” and tension between the human and nonhuman collaborator (see also Glăveanu et al. 2013). Moreover, there is a relationship of trust and tension which mimics the intensity of the human/human relationships described above. Other artists discuss being aware of how material reacts and how they respond to a question posed by the material rather than imposing their imagination on that object (Botella et al. 2013).

Collaboration Across Different Time Scales: The Development of a Shared Possible

When we consider collaboration, it is important to consider it as a process unfolding across multiple time scales. Not only do collaborative creative processes occurs against the backdrop of a particular sociocultural field which structures, constrains, and extends possibilities, they also take place within the different life histories of those collaborating. Thus, collaboration and the

possible take place on different time scales from the micro to the macro. On the one hand, the possible is created at the moment of production, on the other it comes into being as relationships develop between the collaborators. These can almost be conceived as two versions of the possible: an emergent, immediate possible which is grounded in material action and an ever present shadow of an “envisioned” possible which captures the cumulative possibilities for thought and action that come out of experience and that we can more easily reflect on. There is also an explicit tension in considering the relationship between the sociocultural background and the role of the individual in creativity: the novelty inherent in creative acts requires the transgression of the sociocultural norms and yet the evidence suggests that the creative act is at the same time dependent on sociocultural changes.

Collaborations take place against a rich tapestry of ideas, language, and materials and even an individual who doesn't name direct collaborators cannot be fully understood without reference to this. We would extend the concept of collaboration beyond direct collaboration with people and things to describe the dialogue between past and present ideas (see also Ross et al. 2020) where one of us has expanded this idea further). There are fertile moments in history that generate cultural moments from which new creative products emerge (Simonton 2019). Alongside an inspirational social milieu, the material conditions are hugely influential on the levels of creativity and this appears to hold throughout history. Again, what is possible arises from a tension between the individual and the surrounding creative energy which at once extends and constrains the individual. An understanding of the possible as it relates to creativity must take into account the indirect collaborations which arise from a situated individual.

Even those people characterized in the collective imagination as an individual genius are perhaps best understood as arising from this complex and dialogic network of indirect collaborations and sociocultural forces (Ross and Vallée-Tourangeau 2018). Take, for example, the work

of Shakespeare: The modern desire to attribute authorship to one sole individual and grant him ownership of the text is anachronistic when applied to his plays which were generated when ideas of text ownership were not understood as they are today. It is notable that the entire field of authorship studies has now arisen to disentangle the phraseology and words that can be attributed to different single authors from this period. Thus, collaborations are woven into the very fabric of the texts we have inherited (Dahl 2016) and these texts reflect speech patterns and thoughts that cannot be easily attributed to any one person. For example, Marlowe's and Shakespeare's influence on each other until the former's dramatic death was substantive to the extent that there are still many who are convinced that Marlowe is a better candidate for authorship of the plays commonly attributed to Shakespeare. Indeed, Muthukrishna and Henrich (2016) review the history of many modern innovations, such as the light bulb or the theory of natural selection, and show that these are best explained as the result of collaboration and cultural recombination, with little credit given to their supposed inventors (see also Lamb and Easton's theory of multiple discoveries 1984).

Collaboration and Cognitive Modernity: The Possible in Deep Time

Evidence from primatology suggest that wild apes are neophobic, extremely conservative, and avoid innovation where possible (Forss et al. 2016), a situation which stands in stark contrast to the creative nature of modern human societies. However, the exceptional creativity that characterizes our contemporary situation is not evident for much of our deep history. Instead, the archaeological record suggests that for long periods, sometimes spanning millions of years (Finkel and Barkai 2018), we seem to have been little more creative, at least in ways that are evident in the archaeological record, than chimpanzees or other ape species. Perhaps, seen in this light, creativity is not likely to be a particularly fruitful field of

study for those concerned with our species' long-term development. This situation is exacerbated by the fact that archaeology is concerned with long-term patterns and behavioral trends, rather than individual action, and in this context it is extremely unlikely that archaeology will identify creative, or innovative, behavior unless and until that innovation has become widespread among a population and persistent over long-time spans (Hovers and Belfer-Cohen 2006).

Given this, it is clear that the data sets available to prehistorians are not suited to the study of individual creativity and so the recent focus has been not on individual moments of creativity, but more on the social and ecological contexts that encourage creativity (Kuhn 2012). This has been a far more fruitful avenue and seen from this standpoint, creativity becomes an essentially collaborative process. In this section, we will briefly review a selection of archaeological evidence demonstrating that collaboration is a powerful explanatory tool not only for the transmission of creative products but also for the development of creativity itself and finally suggest that creativity in all its forms may be best viewed as an expression of collaborative intent.

Deep History

For vast swathes of our deep history, hominin evolution suggests that our ancestors were not particularly creative, especially in the realm of material culture. For example, the Acheulean handaxe – a bifacially flaked large cutting tool that first appears in the archaeological record around 1.8 million years ago in Africa – remained, essentially unchanged, the tool of choice for over a million years (Finkel and Barkai 2018); a remarkable period of stasis and conservatism. Indeed, many archaeologists (e.g., Mithen 1998) have argued that we do not see real human creativity until the Upper Paleolithic period (around 40,000 years ago) in Western Europe. This period has been characterized as a creative explosion and is marked by rapid diversification in stone

tool styles, flexibility in hunting strategies, and, perhaps most dramatically, a flourishing of both parietal and mobiliary art. Traditionally, many archaeologists have explained this pattern, that is a long term stasis followed by a sudden florescence in creativity, as being a result of a neurological “tweak” in the human mind that created “modern” or creative cognition at around 40,000 years ago (Klein 2000; Mithen 1998).

However, a growing corpus of data now shows that this explanation is untenable (d’Errico and Stringer 2011; McBrearty and Brooks 2000). As we collect more data on the behavior of our Paleolithic ancestors, the evidence indicates that creativity did not emerge in a “big bang” 40,000 years ago. Rather the data now show that creativity (at least durable material creativity) appears and disappears from the archaeological record over a period of several hundred thousand years. For example, Henshilwood et al. (2011) have shown that during the Still Bay period human groups in Southern Africa were making art, jewelry, and bows and arrows around 80,000 years ago, indicating that humans could be exceptionally creative well before the 40,000-year neurological tweak proposed by Mithen and Klein.

Additionally, it is now also recognized that such periods of exceptional creativity, such as the Upper Paleolithic or the Still Bay, did not lead to sustained creativity among our species, rather these periods were followed by long periods of creative stasis. A final nail in the neurological explanation for Upper Paleolithic creativity is provided by the fact that we now have good evidence that Neanderthals were also capable of remarkable creativity including the manufacture of art and jewelry (Finlayson 2019). Taken together, these lines of evidence have led many archaeologists to propose that periods of exceptional creativity are not caused by modifications to the brains of individuals, but rather reflect demographic factors, including population size and the closeness of social networks (Powell et al. 2009).

Demographic models of this type generally assert that large groups of social learners (equipped with the biological and material

equipment to transmit and maintain culture) are more creative than small disconnected groups. Based on model data, Powell et al. (2009) show that not only are large connected populations needed for the transition and maintenance of culture, but also that large populations of closely collaborating individuals are also key for the creative process itself. This model implicitly flags collaborative creative as a key mechanism not only in the transmission and acceptance of innovation but in its actual occurrence. Larger populations are not just more likely to sustain creativity, they are more likely to generate it. Joseph Heinrich and colleague elaborate these ideas and argue that human creativity is essentially an emergent phenomenon of large well-connected populations of social learners (e.g., Muthukrishna and Henrich 2016). Muthukrishna and Henrich argue that innovations mainly occur through serendipity or through cultural recombination which leaves little, if any, role for the individual genius. Demographic models of this ilk provide a far better fit with the archaeological and biological evidence and suggest that throughout our evolutionary past almost all creativity was essentially collaborative in nature.

While these models may explain how large, collaborative human social networks foster creativity, they do raise the question of why we saw so little creativity until the last half a million years of our evolution – as demonstrated by the Acheulean “stasis” discussed above. Here the answer may lie in the not in a neurological “creative” tweak but rather in the development of a suite of cognitive mechanisms that foster close collaboration between groups that may not have been in place until around 500,000 years. Elsewhere, one of us has argued that by around 500,000 years our ancestors possessed the socio cognitive skills and biological capacities (e.g., language, shared intentionality, full theory of mind, and the ability to share plans for the future and reflections on the past) to undertake close collaboration (Underdown and Smith 2019). Additionally, from this time onwards there is good evidence that hominin groups engaged in collaborative

hunting; a major creative development that allowed our ancestors to become the planet’s apex predator (Conard et al. 2015). It may also be significant that 500,000 years ago also marks the period where the Acheulean handaxe is replaced by a more varied a flexible stone tool technology. We argue that, from this point onwards, humans possessed the biological kit needed to collaborate, and that collaborative creativity was now possible whenever demographic and social factors were in place. Collaboration, rather than the development of individual cognitive capacities, may well be what made creativity possible.

Conclusion

Collaborative creativity moves beyond the understanding of creativity as an accumulation of individual units, rather this view takes a broader view of creativity seeing it as emerging from the interaction of people and things. In this way, collaboration is intimately bound up in the possible. Like the possible, it exists across multiple time scales and in the differences between people and things. Furthermore, such collaboration is predicated on a shared sense of the possible and that possible becomes extended through collaboration. Thus, while in collaborative creativity, the possible only becomes visible when it is actualized collapsing the divide between the actual and the possible, it is this shared vision of the possible which motivates collaboration.

Extending back into our deep history, our brief review shows that most (if not all) human creativity appears to have been collaborative in nature and that focus on the links between the individual cognitive process that underlie collaboration coupled with analysis of the social networks and demographic settings of our prehistoric ancestors may provide a powerful means to explain the sporadic appearance of creativity in the past rather than a focus on creativity *per se*. This is in line with much recent thinking that focusses upon the collaborative nature of human cognition in general (e.g., Wilson 2005). According to this

hypothesis, stunning creative achievements are able to be interpreted as visible manifestations of human collaboration.

Keywords

Complexification · Creativity · Disjunction ·
Future · Human Nature · Improvisation ·
Reductionism

Definition

“It’s a complex situation.” “He’s a complex person.” The term *complex* is used with increasing frequency to describe a situation or person that is difficult to understand and know how to deal with. Dictionary definitions refer to a phenomenon or problem with many interconnected parts that is not easy to analyze or understand. The etymology of the word complex is the Latin *complexus*, or “woven together.” Complex problems and complex systems are interconnected, interdependent, and unpredictable. This entry describes and places the work on complexity within the field of the possible.

Introduction

Complexity is not *complication*. A knot that needs to be unraveled can be complicated, meaning the procedure will be time-consuming and requires close attention. A complicated recipe or procedure may involve multiple steps that are individually difficult and may need to be performed with very tight time lines. But the steps themselves are nevertheless clearly laid out, and such a complicated task is fundamentally *algorithmic* and *structured*. Complex problems, on the other hand, involve unstructured processes in unstructured contexts and can therefore be described as *heuristic*. There is uncertainty and unpredictability in both process and outcome. With no set preexisting

rules to be followed, the process itself has to be *created*. To paraphrase the poet Antonio Machado, there is no road to follow, and the path is laid down in walking. The lived experience of complexity requires the ability to respond to the unforeseen as well as generate the unforeseen, to come up with as yet unknown ideas and approaches – in other words, to *create*, explore possibilities, and to *improvise* – the Latin root of improvisation is *improvisus* or unforeseen (Montuori, 2003).

How can human beings deal with an increasingly complex world – interconnected, interdependent, and uncertain? Scholars have argued that we live in “liquid” (Bauman, 2007), or “postnormal,” times (Sardar, 2010), or in the Anthropocene, so named because human activity has become the dominant influence on the environment and climate. A strong argument has been made by systems and complexity scholars that a new way of thinking is needed to address the complexity of the world (Bateson, 1972; Capra & Luisi, 2014; Morin & Kern, 1999). Central to that new thinking is the ability to entertain many possibilities, to differentiate, and to integrate them (Suedfeld et al., 1992), as well as generate many possibilities.

In this entry, following Morin (Morin, 2008a, b) we distinguish between restricted and general complexity. The former refers to what is known in the USA as complexity theory, and the concept of Complex Adaptive Systems (CAS). It uses computers and mathematics to model complex systems. Morin writes that general complexity requires an epistemological shift that includes a reflection on the role of the inquirer and the fundamental principles of thinking, moving from a paradigm of simplification based on reductionism and binary logic to a paradigm of complexity based on distinction and conjunction. I will address these terms more extensively below. The “general” also it refers to a way of thinking, and arguably a worldview, that informs everyday thinking, choices, and decisions in the form of what Morin calls “complex thought.”

This entry begins with an overview of the “paradigm of simplification” (Morin, 2008b) that emerged with Newtonian/Cartesian science.

Starting with Newton, there follows a brief sketch of three scientific paradigms, which in the twentieth century culminated with the emergence of complexity in science and the “creative universe” rather than the machine universe of Newton and Descartes. From there, we transition from the science of complexity to the challenge of complex thought, and the argument that in order to make sense of a world that is interconnected, interdependent, unpredictable, and uncertain, a new kind of thinking is needed. The further challenge of exploring possible futures, and the relative absence of a flourishing discourse about possible positive futures, is, I will argue, due in part to the fact that given the current time of global transition, complex futures cannot be envisioned with a paradigm of simplification.

The Paradigm of Simplification and the Limits of Analysis

Psychologists have found differences in thinking between East Asians and “Westerners” (Nisbett & Miyamoto, 2005), by which they mean the USA, Canada, and Northern Europeans:

Westerners tend to engage in context-independent and analytic perceptual processes by focusing on a salient object independently of its context, whereas Asians tend to engage in context dependent and holistic perceptual processes by attending to the relationship between the object and the context in which the object is located. (p.467).

Analytical thinking refers to the process of separating something into its constituent elements. It is a central aspect of the “paradigm of simplification.” Analysis has become synonymous with “good” thinking in the West,¹ and to say one is going to analyze a problem colloquially means one is going to give it serious, systematic attention, by breaking the problem down into its constituent components.

¹ These are obviously generalizations, because central and southern Europeans are generally found to be more holistic, and Western thought is by no means monolithic. Key figures in the Western intellectual tradition have critiqued the Newtonian Cartesian paradigm. Notable examples include Vico, Goethe, and Blake. Nevertheless, the dominance of the paradigm of simplification cannot be denied.

Key features of the paradigm of simplification include the following (Harman, 1991; Heath-Carpentier, 2022):

Reductionism, or the assumption that complex phenomena must be explained in terms of component, simpler phenomena, and that a whole is explained from the knowledge of its parts. Reductionism involves the search for ever more fundamental, simple, constituents of a phenomenon. Reductionism is a way of thinking and an assumption about the world, namely that it can be reduced to its most basic foundation. On a larger scale, this meant that sociology could be reduced to psychology, then biology, chemistry, and finally physics, which was viewed as the bedrock foundation of everything. For psychologist Viktor Frankl, this form of reductionism was close to nihilism in its “nothing but-ness” (Frankl, 1969), such as when love is reduced to *nothing but* the effect of hormones.

Positivism, the assumption that all that can be known scientifically is derivable from physically measurable quantitative data. Positivism’s attempt to eliminate vague metaphysical statements proved to be too limiting and made it virtually impossible to talk about the most significant aspects of life.

Objectivism, the conviction that the observer is separable from the observed. Cybernetic epistemology, and notably feminist scholars (Code, 1991), rejected the attempt at eliminating the role of the observer. The observer returned to center stage, and in the most sophisticated approaches to complex thought this became an opportunity for self-knowledge and creativity (Heath-Carpentier, 2022; Hodgson, 2020).

Determinism, the doctrine that phenomena can be predicted from knowledge of scientific laws and of their initial conditions. Countering determinism, twentieth-century developments in science, notably quantum physics and chaos theories, have emphasized uncertainty and the extent to which the world is unpredictable (Peat, 2002).

Disjunction, separating with an either/or logic. Disjunction is a process of separation, colloquially referred to as either/or thinking. Many of the dualisms of modernity, such as thinking and feeling, mind and body, and objective and subjective, are examples of disjunctive separation of complex phenomena. It is now becoming clear, for instance, that thinking and feeling as well as mind and body are not separate but profoundly interconnected and interdependent. This also means they are far more complex than previously thought. While it is useful to make *distinctions* between these terms for purposes of orientation and system definition, to *separate* them creates the world of closed noninteracting systems of the Newtonian world (Heath-Carpentier, 2022).

Scientific Origins of Complexity

The scientific study of matter started in the seventeenth century with Newtonian mechanics. The Newtonian universe was portrayed as a giant machine or clockwork. This was a powerful image with profound implications. Human beings began to think of themselves as machines, notably in Julien Offray De La Mettrie’s 1747 *L’homme machine*. Today this machine metaphor is still found in talk of “programming” or “hacking” the brain. “Bodywork,” a term initially used for auto repair, is used for therapeutic massage and physical therapy, and the expression “well-oiled machine” describes efficient organizations or teams.

Scientific innovation led to the advances in technology at the heart of the Industrial Revolution that dramatically changed the world. Inevitably there appeared a fly in the ointment of the well-oiled Newtonian machine. In the nineteenth century, with Rudolf Clausius, Ludwig Boltzmann, and the development of the laws of thermodynamics, the static view of the Newtonian world did not hold. With the second law, Clausius introduced the concept of *entropy*. Entropy is defined as energy that is unavailable for work. The second law of thermodynamics states that in a closed system, entropy never decreases. Entropy involves the spontaneous transformation of order into disorder: Cars will rust, machines wear out,

not all heat is converted to work, the breakdown of patterns and structures will either increase or stay the same, and in the end concepts like clockwork universes run down, too. Rather than a perfect machine, the universe was now seen as gradually moving toward an inevitable heat death. This was arguably the moment when complexity appeared in a Newtonian universe, where the physical laws had been reversible and time did not play a role. With the second law of thermodynamics, this was no longer the case. The arrow of time was introduced, and its role was essentially to tear away at the pristine primal perfection that had been imagined for the world.

At the beginning of the twentieth century, physics could account for dis-organization, but it was unable to account for the organization and reorganization of the Universe. It was still the case that smooth change, predictability, and equilibrium were seen as normal. Complexity, irregularities, and far-from-equilibrium systems could not be studied and as a result were dismissed as peripheral. Linear phenomena change slowly and in predictable ways. They are analyzable, predictable, and controllable. The nonlinear equations necessary to address more complex, unpredictable phenomena had to await the power of computers and the birth of complexity theory. The concept of emergence, “nature’s creativity” (Rue, 2007), and new developments in evolutionary theory pointed to the creative, innovative nature of the universe (Bocchi & Ceruti, 2002; Ceruti, 2008).

The physicist Paul Davies summarizes the next paradigmatic development (Davies, 1989):

Now there is the paradigm of the creative universe, which recognizes the progressive, innovative character of physical processes. The new paradigm emphasizes the collective, cooperative, and organizational aspects of nature; its perspective is synthetic and holistic rather than analytic and reductionist. (p.2).

As Davies suggests, in the new view the universe is interconnected, interdependent, and actively *creative* of new phenomena and processes. He also makes the crucial point that a different approach is needed to understand this creative universe. The analytic, reductionist

approach which focused on breaking phenomena down to their most basic components could not account for how components were connected, the result of their interactions, the systemic properties of the whole, and the emergence of novelty.

What is needed to understand this new universe is a kind of thought that is systemic and creative – in other words, complex. The synthetic and holistic approaches Davies speaks of, appropriate for a complex world, did not have to be invented out of whole cloth. They had a tradition in western thought. The precursors of today’s science of complexity include the tradition of Holism, as in the German Gestalt school (Ash, 1998; Harrington, 1996), and more specifically in the development of General System Theory (GST) (Von Bertalanffy, 1976), Cybernetics, and Information Theory (Bateson, 2002; Maruyama, 1974; Morin, 2008a). Indigenous science and Buddhism are also highly sophisticated systemic understandings of an interconnected world and are now increasingly in dialogue with systems and complexity science (Cajete, 2000; Macy, 1991; Yunkaporta, 2020).

Cybernetics introduced the concepts of feedback and mutual causality. Negative feedback is deviation-reducing feedback, as in a thermostat. A decrease in temperature below a certain threshold kicks in the heating, so that a relatively stable temperature is maintained. Positive feedback occurs in so-called “self-exciting” or “run-away” systems when one person’s rude behavior leads another person to respond even more rudely and the interaction escalates until the arrival of the police acts as negative feedback. Positive feedback can be found both in vicious and virtuous cycles. Individuals who do not exercise tend to feel more and more out of shape and therefore do not feel like exercising, which makes them even more out of shape; as a result, they are even less likely to move, and so on. Positive feedback can also kick-start a situation that has become stuck. The more a person exercises, the better they feel, and so they are likely to keep exercising.

The notion of the feedback loop takes us beyond linear causality. Linear causality works in a straight line: A causes B, which causes C. In

cybernetic or mutual causality, we can see how A causes B while B causes A. This dynamic of mutual causality is found in interpersonal relations. John reacts to Mary's behavior, but Mary's behavior was in fact a reaction to seeing John. This can create scenarios where John might think Mary is angry at him, and therefore approaches her defensively. Meanwhile, Mary thinks John is acting aggressively and so responds in kind, in an ongoing spiral of misunderstanding. The causality is mutual, and any attempt to reduce it to a linear dynamic typically descends all too soon into "you started it," "no, you did." This is why therapists with a systemic orientation tend to avoid going back in time to see "who started it" and focus on the patterns of behavior that keep the problem going (Smith-Acuna, 2011).

Cybernetic epistemology, or second-order cybernetics, involves the study of *observing* systems, rather than *observed* systems (von Foerster, 2003). It introduced the role of the observer (researcher) into the research process, making the observer a participant rather than a bystander. This participatory approach provided an alternative to the more traditional approach of attempting to eliminate or at least disguise the observer in a quest for objectivity. Cybernetic epistemology pointed to the importance of self-reflection, an awareness of circularity and of the larger assumptions that influenced inquirers, as well as a sensitivity for the ever-present possibilities of errors, illusions, and self-deception, and the creative dimension of inquiry.

General System Theory (GST) has made the useful distinctions between system and environment, part and whole, and the central concept of the open system. From a systems perspective, in the Newtonian view the whole world is made up of closed systems. Rather than self-contained "atoms," open systems are in a constant exchange of matter/energy with their environment. This is very clear in all living systems. From the perspective of GST, any open system needs to be studied in its context. This means including its exchanges with its environment, rather than abstracting it in a laboratory setting. Abstracting here specifically (and etymologically) means removing from its context.

The implications of this view extend to the very notion of identity. As Morin (Heath-Carpentier, 2022) points out,

we arrive at what I logically call the autonomy/dependence complex. For a living being to be autonomous, it must depend on its environment for matter and energy as well as knowledge and information. The more autonomy develops, the more multiple dependencies develop. The more my computer allows me to have an autonomous thought, the more it will depend on electricity, networks, and sociological and material constraints. We arrive then at a new complexity for the living organization: autonomy cannot be understood separate from its broader ecology.

A fundamental tenet of GST is that the behavior of systems cannot be understood through an analysis of the parts that make up the system. A complex system is more than the sum of its parts. Complex systems, which can range from the global economy to ecosystems to the human brain, have *emergent properties*, or systemic properties, that cannot be predicted from the behavior of the individual parts but are the result of their interactions (Johnson, 2001). Water is a classic example, as two hydrogen atoms and one oxygen atom combine to form a molecule of water – water is an emergent property.

Open systems survive only through a constant exchange of matter/energy and information with the environment. An open system is stabilized by this ongoing flow. Not enough input, and a living system dies. Too much input, and the system is overwhelmed, which can force drastic change. When certain levels of fluctuations are created by increasingly complex input, a critical or *bifurcation* point is reached. At that point, the system can move in any one of several directions until, after a period of turbulence, a higher, more complex order may be established. If a higher order does not emerge, the system returns to a lower level of organization (Prigogine & Stengers, 1984).

In the traditional Newtonian scientific paradigm, order was king, privileged above disorder, chaos, and "noise." The relationship between order and disorder was viewed as a hierarchical binary opposition. Disorder was viewed as a function of human ignorance, something that would,

eventually, with more and better knowledge, be integrated in the larger master plan. The world was assumed to be fully knowable and predictable. Reality may have *appeared* complex, but its true nature was simplicity.

One of the most interesting shifts in recent scientific thought, in particular because of the sciences of cybernetics, chaos, and complexity, has been a deeper understanding of the mutually constitutive relationship between order and disorder, information and noise. This shift also reflects a transition from a fundamentally static, orderly Newtonian view of the world, to one that is process oriented. Rather than a fundamental and unchanging order, there is an ongoing process: The interaction of order and disorder takes form in the process of (self-) organization. In the creative universe, disorder not only destroys structures, systems, and organizations, but it is also central to their development and regeneration. The interaction of order and disorder can be generative of new forms of organization, and any order is the result of an ongoing process, not of preestablished forms. It should perhaps come as no surprise that research shows creative individuals have a preference for complexity and also for disorder, but only to the extent that it can be, through a creative process, integrated into a higher order (Barron et al., 1997).

Self-organization has been defined variously as making meaning out of randomness, or the spontaneous emergence of a coordinated and collective behavior in a population of elements (Atlan, 2011). One of the key aspects of self-organization is the integration of perceived as disorder into a larger, more encompassing organization. This also led to Von Foerster's principle of "order from noise," Atlan's "complexity from noise," and Prigogine's "order out of chaos" (Atlan, 2011; Prigogine & Stengers, 1984; von Foerster, 2003).

Complex systems are on the edge of chaos, on the knife edge between order and disorder, and it is here that creativity is possible. The system is neither completely chaotic, or so orderly that nothing new can come in or come out. The philosopher Mark Taylor summarizes (Taylor, 2003):

(A)ccording to complexity theorists, all significant change takes place between too much and too little order. When there is too much order, systems are frozen, and cannot change; and when there is too little order, systems disintegrate and can no longer function. ... According to [Ilya] Prigogine disorder does not merely destroy order, structure, and organization, but is also a condition of their formation and transformation. New dynamic states. . . emerge in conditions far from equilibrium. . . . Complex adaptive systems. . . always emerge at the edge of chaos. . . [and] are in a state of continual evolution. (p.14–15)

Slime molds spend much of their lives as individual single-celled units but come together at various times to form one large organism. How this happened remained a mystery for a long time. The assumption was always that there was a "pacemaker," a leader of some sort (Johnson, 2001). Human beings are used to thinking of organization as hierarchical, with a leader at the top, and so this model was transplanted onto slime molds. It took at least a decade after Evelyn Fox Keller proposed that there was no pacemaker, and the process was bottom-up, self-organizing, with no pacemaker or leader, for the idea to have a real impact in the scientific community (Keller, 1983).

This example is an indication of how the emerging systems and complexity sciences led to a shift in thinking about the world. Another example comes from systemic family therapy. The very notion of a child being brought to therapy as, and with, a "problem" was challenged by systemic family therapists. Their argument was that the child's behavior could be a symptom of the larger dynamics in the family rather than a reflection of something being "wrong" with the child. More broadly, this has also manifested in a critique of the focus on blame in addressing problems. Systemically oriented thinkers have challenged the notion of a single source and cause of a problem, which results in someone or something to blame, in order to expose the dynamics of systems that contribute to problems, in contexts ranging from family therapy to the study of accidents (Newnam & Goode, 2015).

An extreme example of reduction and disjunction is found in political rhetoric (Montuori, 2005). The focus is on one particular group as

the source of all of society's troubles (immigrants, Jews, and people of color) then a sharp, absolutizing separation between "us" and "them," where "they" are evil and "we" are good. This is an example of the paradigm of simplification taken to its political extreme, and an all-too frequent page from the authoritarian playbook. During times of crisis, this strategy of simplification appears to cut through the complexity with a clear and distinct solution, hence its appeal. But it also is the case that while this polarized focus on an enemy may unite, the results are almost invariably catastrophic (Thompson, 1976).

Thinking Complexity

Transdisciplinarity and Complexity

The explicit goal of many of the pioneers of systems theory and cybernetics was to develop a language and a way of thinking that could move across the proliferation of mostly non-communicating disciplines (Bateson, 2004). They also sought greater communication between and integration of all the sciences and expressed their concern about increasing disciplinary fragmentation. In their view, any systemic inquiry studied a system in its environment, and was therefore almost inevitably an inter- or transdisciplinary project.

Transdisciplinarity has emerged in recent years as an approach to address "wicked" problems, so-called because of the difficulty in solving them as a result of their complexity (Martin, 2017). Wicked problems cannot be solved from the perspective of only one discipline. This means large public projects, for instance, must draw on scholars and expertise from a number of different disciplines. Wicked problems are systemic problems requiring systemic approaches. They form an interconnected system, there is a high degree of uncertainty, there are no preexisting ways to address them, and there are a plurality of possible perspectives and ways to approach them.

Transdisciplinarity is not only of use for tackling wicked problems. It can also be used to explore current understandings of phenomena,

such as creativity. A transdisciplinary approach is grounded in systems theory and complex thought. As a result, it would reject the assumption so central to creativity research for many years that the *who* of creativity research should be an individual abstracted from their context. From a systems view, any phenomenon should be studied by taking into account its relationship with its environment. As a result, a systems approach will almost inevitably take the researcher outside their disciplinary boundaries, adding to the complexity of the task. A psychologist faced with histories of prejudice and exclusion toward women in the arts and sciences, for instance (Eisler et al., 2016), may find this topic has received attention in sociological and feminist studies, but not psychology. A systems approach would require a more complex approach, a weaving together of information and meaning, and the development of transdisciplinary scholarship and collaborations across disciplines. A transdisciplinary approach would also explicitly incorporate creativity as central to the process of inquiry.

Creativity and Complexity

In the new view, the universe is creative and systemic in nature (Kauffman, 2016; Swimme & Tucker, 2011). Likewise, the problems currently facing humanity, such as climate change, terrorism pandemics, political instability, and immigration, are systemic in nature and require creative responses. Complexity is not only profound interconnectedness, but also profound creativity. But creativity was historically viewed as a phenomenon that manifested only in very few unique individuals (Montuori & Purser, 1995). It was a gift, a blessing, and a curse. It was also a mystery, and therefore not something that could be reproduced or taught or shared. As a result, creativity has not been an integral part of western educational systems. In fact, education was not intended to promote creativity. Educational systems were designed to produce people for the industrial age who could perform well in the assembly-line, in the mass production world of industry or government bureaucracy. Education itself took on an

assembly-like, mass production quality which emphasized the reproduction of information, the reproduction of workers who could fit in this orderly world, and the reproduction of the social order and hierarchy (Montuori, 2011b; Spring, 1994).

One reason for the absence of creativity was that following the Industrial Revolution there developed a split between Positivists and Romantics, with, in broad terms, positivism on the side of science and the romantics on the side of art (Brown, 1977; McGilchrist, 2009). For the science of the time, creativity was too unpredictable, subjective, not law-like enough, and essentially *too complex* to be studied scientifically. As a result, science presented itself as objective, coolly rational, and methodical. It omitted the subjective, creative experiences of scientists making breakthroughs.

With the split between Positivism and Romanticism, creativity ended up in the Romantic camp, where it was later popularized, commercialized, and oversimplified as the lone genius myth (Montuori & Purser, 1995; Stigliano, 1999). Deprived of creativity, academic inquiry described itself as a rather anemic, dull, systematic, methodical process that involved the accumulation and categorization of facts and the application of the scientific method with the goal of certainty, order, and prediction (Maslow, 1969).

It was far from clear how the scientific method actually leads to great scientific discoveries, because it was only in the biographies and autobiographies of scientists that readers learned about the realities of what actually happened leading up to great inventions and discoveries besides methodical systematic work: serendipitous discoveries (e.g., Fleming and penicillin), dreamy insights (Kekule and the benzene ring), visualization, *gedankenexperimenten* (Einstein riding a beam of light), the humor of Richard Feynman's spinning plates, and so on (Barron et al., 1997; Irvine, 2015). The actual creative process was not considered scientific or for that matter philosophical, yet it is clear that in practice the creative process lies at the core of all inquiry.

The focus in education all over the industrial world has overwhelmingly been on information,

categorization, and analysis of *what is*, rather than explorations of what *could be*. It is not surprising that one main way of showing one's intelligence in academia is through the ability to shoot down ideas, to exercise one's critical acumen. The cultivation of critical thinking is paramount, but little attention is placed on the kind of exploration of ideas, possibilities, and support of creative thinking necessary in the twenty-first century.

The analysis of what is, and the emphasis on critique, does not prepare students to deal with the possible, the unexpected, and does not encourage entertaining ideas for fear of being dismissed or ridiculed for presenting an idea that does not fit into what is currently accepted. The neuroscientist Gregory Burns has argued that fear of failure and public ridicule are key hindrances to the development of creativity (Burns, 2010). Ideas often emerge as fragile wisps that need to be cultivated, nurtured, and articulated before they can be critiqued. Possibilities will continue to be generated and explored in an environment that supports such a process. A too harsh environment will kill off ideas before they had a chance to develop, reducing the openness to possibility, and the willingness to stick one's neck out with a possibility rather than a certainty.

It would not be an exaggeration to say that the educational systems all across the world have sadly focused on learning to read music and develop instrumental skills, but they have not supported the education of students to generate and explore possibilities and make their own music. A musical analogy might illustrate the difference between the educational model that emerged from the industrial age and what is needed today, using western classical music and jazz as examples. The point here of course is not which type of music is better, but the nature of the skills developed in order to become an expert instrumentalist. For the industrial age, western classical musician learning to read music was essential, and the purpose was to learn to play the music of the great composers. For what we might call the musician in the age of complexity, learning to read music is not enough – it is also essential to be able to improvise, to compose in real time, on the spot, during a performance. The

latter is of course the model of jazz. In the former, all the musical possibilities are preestablished by the composer. In the latter, the musician has to be able to explore and perform live drawing on a range of possibilities in terms of their contribution to a particular piece. The possibilities range from the sound they choose to use on their instrument, the choice of notes, the interpretation of the mood of the song, and the vision of the bandleader, and so on (Berliner, 1994; Montuori, 2003).

Interestingly, before the industrial revolution there was a great tradition of improvisation in western music, and the great composers were also known as great improvisers. With the capitalist machine industrial model that emerged in the nineteenth century, the mythology of the genius composer, and the development of copyright, improvisation was discouraged and eventually eliminated from western classical music. Essentially, this meant that the range of possibilities in terms of choice of notes to play was reduced to zero. The composer's music could be *interpreted* in a limited number of ways, but the actual composition was entirely the composer's. In jazz, the compositions, such as the Great American Songbook, provide a vehicle, a mood, and a set of chord changes for the instrumentalists to explore, which means develop the possibilities inherent in the song, in their own playing, and the relationship between the two in the moment. As I have argued elsewhere, skillful improvisation can be seen as the embodiment of complexity – of systemic creativity, relational and generative: a dance of constraints and possibilities.

Possibilities, Constraints, and Complex Creativity

The most important task today is, perhaps, to learn to think in the new way Bateson, 1972, p.462.

The future is the horizon of human possibilities. And yet a review of the last 50 years ago leads us to think the “possibilities” for our world appear to be rather grim. Are there possibilities for a *better* world in a time when the dark clouds of environmental collapse, political, economic, and social

instability, and the resurgence of authoritarianism feature among many of the current global troubles? Terms like utopia, progress, and even the milder term “better” futures have had to make place for an avalanche of dystopian and post-apocalyptic imagery. Popular culture shows the popularity of dystopian and postapocalyptic literature and cinema. The optimism of modernity is gone, and in its place a generalized postmodern mood of pessimism and critique (Ogilvy, 2011).

The larger context is a global transition from one age – modernity, the industrial age – to an as yet unformed “next” age (Fraser, 2019; Kelly, 2021; Sardar, 2010). The present condition is postmodern, postnormal, or among many other terms, the Anthropocene, which essentially says humans are now responsible for changes in the environment. The dystopian images arguably reflect not only the death of one “world,” of modernity, but also the relative absence of alternative visions, of what is next, with some notable exceptions (Kelly, 2021; Morin & Kern, 1999).

Postmodernism developed a critique of modernity, attacking its faith in reason, science, and “metanarratives” such as progress. It challenged, among other things, assumptions of rationality, linear progress, demarcations between “civilized” and “primitive,” and the scientific veneer that hid practices of domination. In case this seems rather abstract, 2 World Wars and several centuries of inhuman colonization and a legacy of racism have, for many, shattered the west's image of progress and human betterment. Precisely the features of modernity that were initially viewed with great hope – science, technology, industry, and democracy – are viewed by many with a “hermeneutics of suspicion.” The pandemic has highlighted the growing distrust in government, big science, media, and industry.

At the beginning of the twenty-first century, the critique of *what is* continues unabated. What is missing is a sense of alternatives – of *possibilities*, a sense of *what could be*. And not just any possibilities, but *positive* possibilities. There are movements *against* the forces that aggravate climate change and environmental catastrophe, against racism and misogyny, but interestingly there has been much less clarity about things one can be *for*.

Critics of environmentalism, as well as gender and racial justice, of what Inglehart (Inglehart, 1977) called “the Silent Revolution,” have it easier, in a way: They can critique, but they also have an image (albeit largely imaginary) of the “good old days,” an image of a past they wish to return to.

One can bravely speak truth to power, but ultimately that always assumes it is *others* who have the power, and that it is highly unlikely the situation will change. As a result, it is also not clear what being *in* power would actually mean. But is it not enough to be against something – or many things? Why would it be necessary to explore possible alternative scenarios? Why would it be necessary to show what is desired, what is aspired to, and in the realm of the possible?

Psychologists differentiate between avoid and approach motivation (Elliot & Covington, 2001). Avoid motivations are for the things we do not want; approach motivations are for the things we do want. In a global context, there are currently more avoid motivations than most people can remember, but the approach motivations are lacking. The assumptions about the global situations are fairly dire, and in the United States and elsewhere there is an increase in narcissism, a turning inward away from the world’s troubles, represented most emblematically by the selfie (Masters, 2010; Nordensvard, 2014; Twenge & Campbell, 2010). One reason why the moon landings are remembered fondly in the United States is because there was a sense of collective mission, an opening of possibilities in what was viewed as a new frontier. There was a sense of exceptional effort, exceptional goals, and exceptional possibilities. That sense of possibilities is now lacking, as the focus is more on avoiding dire possibilities. Even if the dire possibilities are avoided, what is there to look forward to?

Not having examples of the possible and a sense of desirable possible futures reduces the sense of *hope* for the future (Lopez, 2013), a sense that the resistance against domination is not just an ongoing endless Sisyphean struggle, where hope is defined by Edwards and McClintock (Edwards & McClintock, 2018) as “the perceived ability to produce energy and avenues around obstacles to

work toward goals” (p.96). A sense of possibilities provides hope, and without hope there is a further narrowing of possibilities in an ongoing negative feedback loop into inaction and depression. A sense of hopelessness is associated with increased risk of suicide, such as America’s “epidemic of despair” (Case & Deaton, 2020; Gidley, 2001; Reading, 2004). This tragic phenomenon was first associated with middle-aged white men but since then has increasingly included Latin and African-American men, individuals who see no hope for their future. They feel the future does not include them, and the doors of possibilities have all shut.

The focus on critique and specifically the critique of narratives that presented science and western civilization as unquestionably beneficent has created a hesitation in presenting any “positive” alternatives. Thinking about the future has become problematic. Thinking about post-apocalyptic futures is in vogue, and thinking about nonapocalyptic futures has become rather difficult and infrequent. What replaces utopias and progress and the illusion of linear betterment? What are the criteria for “better” futures? Higher wages and GNP?

The Millennial generation will be the first in the USA to not be as well off financially as their parents (Luhby, 2020, January 11). But it is not all economics. The capitalist economy is built on the creation of a sense of lack – the need to have something more, and offers endless possibilities in terms of the new and desirable. The economy is built on the belief that whatever is is not sufficient, that there is always something lacking. The burgeoning New Age movement with its emphasis on personal growth and possibilities beyond the material suggests that in a postmaterial culture (Inglehart, 2018) there is a continuing search for something more – new possibilities, in new domains, and specifically, with meditation, yoga, and a variety of other practices, ways of dealing with stress – a stress that includes having *more* choices than before.

It should not be surprising that during this period of high anxiety, one that the US Armed Forces refer to as VUCA – volatile, uncertain, complex, and ambiguous – along with a greater

focus on the self, there is also a trend toward a monoculture dominated by the language of business and economics (Michaels, 2011). It reduces everything to the lowest common denominator, to what is quantifiable, to metrics, and to return on investment precisely because numbers seem “real” and give the illusion of being unquestionable and “objective” as opposed to emotional and subjective and uncertain.

“Futurists,” as they were once called, have, in very broad strokes, gone from prediction (“The World in the year 2000!”) to scenarios (“What if the Saudis created an oil embargo?”), from a reductionist and linear approach to a more complex approach (Inayatullah, 2002). Scenario planning involves assessing possible future scenarios for purposes of preparedness. It has been very successful as a practice (Ogilvy, 2002). But normative scenarios, scenarios that reflect values and are not so much “what ifs” but “why nots,” are harder to come by. A recurring question that has to be asked in the context of the possibilities of the future and the future of possibilities is, what do human beings want? What is humanity already creating, and will it take responsibility for its creations?

Complex Moods

We have seen how the transition from modernity to postmodernity has brought with it a mood of pessimism, a lack of hope, and a seeming inability or unwillingness to envision positive possible futures. Grand sweeping visions of the future are a thing of the past. But does that mean there can be no visions at all, or only fragments of visions or simply brief rejoicing at the appearance of a new iPhone as a diversion during a revolution of lowered (but still expensive) expectations?

In the binary paradigm of simplicity, optimism and pessimism are framed in a binary, exclusive way. Either optimism or pessimism. Today, the latter prevails. Ogilvy proposes a *tragicomic* mood which combines utopian optimism with the awareness of pessimistic possibilities, and the recognition that tragedy may always be closer than we think (Ogilvy, 2011). In a similar vein, Viktor Frankl referred to the attitude of Tragic Optimism as remaining optimistic in the face of

pain, guilt, and death (Frankl, 1985). Images of the future have often been utopian in nature, and suffused with a sense of (somebody’s) “perfection,” but this “dialogical” approach takes the future out of the realm of the strictly imaginary perfect into the “real,” in the sense that if anything, the real is uncertain and unpredictable.

The shift from a simple opposition of optimism and pessimism to a more complex vision recognizes a broader *range* of the possible, as well as the interaction between the terms. This complex approach eschews the excesses of Pollyanna optimism and desperate pessimism, translates into the ability to act in a way that aspires to wisdom, letting go of desires for perfect solutions and master plans, but nevertheless powerful enough to motivate action.

This approach also recognizes the ecology of action (Morin, 2008b), meaning that ideas and actions with the best intentions can turn into their opposites because once they are included in the web of the world’s actions and interactions they can no longer be controlled. A complex approach recognizes that more possibilities also increase the role of uncertainty, of the unpredictable, and the need to navigate the unforeseen in a way that is elegantly improvisational.

The Heart of Simplicity and Complexity

As we saw earlier, at the heart of modernity was Newtonian/Cartesian science with its emphasis on what Morin calls the paradigm of simplicity. The current impasse or crisis of the future is to a large extent the result of this privileging of simple, decontextualized, binary thinking of the paradigm of simplicity. It is not clear that new alternatives and possibilities can be created with the thinking and the worldview of modernity without reproducing those very problems it created. The paradigm of simplicity’s ability to envision desirable possible future appears to be exhausted.

As an example, the creativity of modernity was fundamentally decontextualized and riddled with hierarchical binary oppositions such as Society/Nature, Objective/Subjective, and Male/Female. It privileged the individual against society, society against nature, and particularly with the rise of

capitalism and the industrial revolution, it viewed the environment, both natural and human, as a resource to be used and abused (Montuori & Purser, 1995). It did not recognize that, in the words of Gregory Bateson (Bateson, 1972), “(T) he unit of survival is organism plus environment. We are learning by bitter experience that the organism which destroys its environment destroys itself” (p.484). Attempting to solve the problems created by the paradigm of simplicity with solutions and alternatives drawn from that same paradigm risks recreating the same problems. Despite claims to the contrary from industry, not all innovation is “good,” nor are strategies of “moving fast and breaking things” and of disruption. The much vaunted Bitcoin consumes vast amounts of electricity and produces huge amounts of e-waste.

With modernity, western creativity was conceptualized as a pair with destruction. This can be seen in Schumpeter’s famous notion of creative destruction (Schumpeter et al., 2011) which has so influenced current notions of disruption in industry. But what is clearly missing in this dyad is the reconciling third, conservation, which is found in the Hindu Trimurti of Brahma the creator, Shiva the destroyer, and Vishnu the preserver. A more systemic, contextual, ecological, complex view of creativity points in the direction of such approaches as regenerative cultures and systemic biomimicry (Wahl, 2016), toward a realm of new possibilities that rejects exploitation in favor of systemic wisdom and win/win collaboration. It also points to a new realm of creativity that has generally been overlooked in the West, namely the creation of environments which foster creativity, with their traditions, support, community, and so on. The possibilities must emerge from a different set of principles – a different paradigm that is fundamentally creative and aims to create win/win rather than zero-sum relations.

American futurists Naisbitt and Aburdene (1990) wrote that “The most exciting breakthroughs of the twenty-first century will not occur because of technology, but because of an expanding concept of what it means to be human” (p. 16). Possibilities are always matched with constraints (Ceruti, 2015). Some of these constraints have to do with what is considered

possible in the first place, and they are constraints that pertain to assumptions about the nature of humanity, what Naisbitt and Aburdene call the concept of being a human. Are human beings all out for themselves? Are they fundamentally good or bad? Trustworthy? Is the world a cruel and unjust place? It has been popular in academia to claim that there is no such thing as human nature, to portray the newborn as a blank slate shaped by culture. This argument has been strongly critiqued by Steven Pinker (Pinker, 2002). Whether there actually is or is not a human nature, human beings certainly act *as if* there is a human nature and act on the basis of their assessment. If I believe other people are out to get me, that it is a jungle out there, and I need to take care of only myself, and if I believe in a zero-sum world, I will behave in a different way than if I believe human beings have a capacity for goodness, kindness, and collaboration and that “we’re all in the same boat.” My behavior is also likely to be a self-fulfilling prophecy, as we saw earlier in the discussion of mutual causality in interpersonal relations. If I act in a way that reflects a belief in a zero-sum world, it is very likely others will respond to me in that same way, and I will in fact be contributing to the cocreation of a zero-sum world.

Assumptions about human nature have historically been made explicit by some philosophers (Fromm & Xirau, 1968), novelists, and psychologists, and more recently they have been heard in the sayings of business leaders as they discuss their successes. Amazon’s Jeff Bezos believes human beings are fundamentally lazy and makes that assumption central to the way Amazon works. ENRON’s Jeff Skilling drew heavily on his (mis?)reading of Richard Dawkins’ *The Selfish Gene* (Dawkins, 1976). The writings of Ayn Rand have inspired many American politicians and technology billionaires to see the world and human relations in purely transactional, Social Darwinian terms (Achterhuis, 2010). These so-called philosophies, these assumptions about the world, are usually not explicit and remain unchallenged but inform what is and is not considered possible.

Deep-seated, often unconscious assumptions and beliefs determine to a large extent what is

believed to be possible and what not (Bateson, 1972). This is why it is essential to integrate the inquirer into the inquiry, to reflect on one's assumptions, one's potential for self-deception, and intellectual vices, and to become more aware of how human beings construct their understanding of the world (Cassam, 2019; Morin & Kern, 1999).

Business theorist Douglas McGregor differentiated between Theory X and Theory Y, Theory X being Bezos' view that humans are lazy, unmotivated, and will not take responsibility, whereas Theory Y argues humans are self-motivated, want to be involved in decisions, seek to excel, and so on (McGregor, 1966). The two approaches lead to radically different ways of organizing, and different beliefs about what is possible and how people should be treated. In other words, from a complexity perspective the two descriptions do not describe dueling versions of *what is*, but rather two choices of what could be, of what is possible and what can and will be created.

For the philosopher Cornelius Castoriadis in order to determine the health of a society – or an organization, or even an individual, I would argue – the key question to ask is the extent to which it can recognize in its institution its own self-creation (Castoriadis, 1997). The question then becomes what are humans always already creating? How are their creations a reflection of their beliefs about constraints and possibilities in the nature and capacities of humans and the world? These beliefs about constraints and possibilities, beliefs that self-define humans, are in fact *also* created by humans, and as Morin would argue, human creation is self-eco-creation, because there is no creation without an environment, without relationship, and without a larger context.

It seems there is little doubt that conceptions of human nature and of human possibilities play a key role in humanity's ability to envision possibilities for the future. We have seen how these conceptions of human nature play a central role in reality-creation. We also know that conceptions about human nature and the world play a role in political orientation. Conservatives, for instance,

generally have less faith in the human capacity for goodness and believe that the world is a more dangerous place than liberals (Jost et al., 2009). This suggests the importance of future research on folk views of human nature and the world, and more clarification about existing research in these areas, something Steven Pinker has attempted to do with mixed reviews.

The Creativity of Possibility and the Possibility of Creativity

Creativity has historically been a key driver of possibilities (Glăveanu, 2018). One of the great gifts of creativity is that it allows human beings to see that the world could be otherwise. Creativity in the west has historically been associated with art, science, and technology, and specifically with the creation of objects or ideas. These objects and ideas have in turn enormously expanded the realm of the possible – one need only think about the transformation of transportation in the twentieth century and the possibility not only of travel, but also of mass travel.

Modernity's image of creativity was the lone genius, the individual creator (Glăveanu, 2010; Montuori & Purser, 1995). Postmodern thinkers critiqued creativity as a concept identified with novelty, originality, and exceptional individuals (Kearney, 1988), but the emerging complex, relational alternative shows a creative process that is not *ex nihilo* but the result of interactions in and with culture(s), with a network of relationships, collaborations, and of everyday creativity (Glăveanu, 2014; Montuori, 2011a). This points to a shift in the discourse and practices of creativity that does not deny the existence of genius, but expands creativity to include everyday relational activities by "everyday" people in all sorts of contexts. In an interconnected, complex, uncertain world, this kind of everyday relational creativity is very much needed and creates an ecology of creativity. The quest is now to understand how creativity can be mobilized to actualize human possibilities, in a process of self-creation.

Modernity's creativity was marked by a focus on the sciences and the arts, on the creation of exceptional products. Beyond products, it is humanity itself that is in need of creativity and

exploration of possibilities. The sociologist Anthony Elliott has argued that self-creation in the form of reinvention is now a new form of individualism – the individual who is continually reinventing themselves drawing on a range of possibilities from plastic surgery to continuing education, new jobs, new communities, new sexual identities, and so on (Elliott, 2013). In a world of increasing possibilities, this also raises questions about the responsibilities humans take for their choices, for the possibilities they choose to explore and embody.

Another area in need of creativity and an expansion in the range of what is possible is the admittedly broad domain of human relationships and interactions. With the increasing diversification and pluralism in the world, learning how to communicate across differences and retaining a balance of unity in diversity is a task that will require a great deal of creativity, and the generation and recognition of many possibilities. There is now a recognition of the actual *existence* of collaborative, relational creativity, which was rather a long time coming in the United States, a highly individualistic country. In younger generations that grew up with the Internet and a networked world, creativity is already viewed as more relational and “everyday” (Montuori, 2011a; Pachucki et al., 2010). The development of generative ways for humans to interact, moving beyond the limitations of zero-sum to win-win relationships, has taken on a new sense of urgency. There is a great need to increase the collective capacity of human beings to thrive together (Donnelly, 2016), finding new ways to collaborate and communicate beyond the polarizing culture of argument, polarization, and entrenchment (Tannen, 1999), and moving toward finding mutually beneficial, win-win solutions for problems. This means both opening up more possibilities and also remaining open to possibilities, in a dual, mutually reinforcing process. In other words, it will require a reflection on human possibilities, on the way that cultures create different conceptions of self and other, and accompanying assumptions and practices about identity, collaboration, and creativity.

Summary

Scientific advances in the twentieth century have outlined a new view of the universe, with profound implications for humanity’s understanding of itself. At the same time, humanity is facing serious challenges ranging from climate change to pandemics to economic inequality and the quest for social justice. If indeed, as many scholars have argued, humanity is currently in a transition between ages, suffering through the death of one age while a new age is as yet unborn, new approaches and possibilities will need to be imagined, articulated, and put into practice. It is becoming increasingly clear humanity cannot face these challenges with a paradigm of simplification, the very paradigm that created the current situation. The paradigm of complexity offers a way to address interconnectedness and interdependence, but also to embrace creativity and take responsibility for creating the possibilities from which the future will emerge.

Definition

Computer Science is the branch of science that focuses on computational machines, machines whose primary purpose is process data and to automate tasks. It is a discipline that makes a synthesis between applied mathematics, engineering, electronics, signal processing and uses results from many other sciences to progress. It began as a number processing technology and, since most information can be encoded as digital data, it now concerns most aspects of everyday life; it is now the science of information. With the power of today's computers and the everlasting, computer science seems to open an infinite number of possible applications, such that science fiction sometimes appears not so fictional anymore. Nevertheless, computer science is not limited to its applications and the heart of the discipline indeed consists in designing algorithms to solve problems more efficiently and in identifying limits to what is possible under today's computing paradigms and what is not, what is easy and what is complex.

Introduction

Computer Science is the science that studies information and all its manipulations. More than the design of computers, it focuses on data and the algorithms that transform data so that they can be cleaned, stored, communicated, transformed and interpreted to create information that humans use for taking decision or turn into knowledge. It also provides an interface to the physical world

through sensors, electronic devices that acquire data, and command devices that turn data into actions.

It is a discipline that may easily be an emblem for the post-war society. It started as a simple technical tool for the military and scientists and has now infiltrated every aspect of our lives. The computer, as the main embodiment and support of computer science, keeps getting more powerful following Moore's empirical conjectures (Moore 1975). As it lies at the crossroad of other sciences, it benefits from the discoveries in material and quantum physics, electronics, mathematics, and even borrows from sociology and life sciences.

In the present entry, we will first take a historical perspective to understand where we are today and what are the possible evolutions of technology itself, and of its implications for society. We will first look at the computer as the evolution of computation machines. We will then briefly evoke the interactions between fiction and technology before focusing briefly on live topics such as Artificial Intelligence and cybersecurity. We will then look at today's limits and cover a few research directions.

From Computing Machines to Computer Science

The first machines designed to automate computation can be traced back to ancient Greece, with the Antikythera mechanism (abt. 200 B.C.), a mechanical machine that calculates solar and lunar eclipses dates. Throughout history, mathematicians like Al Jazari (abt. 1200) or Pascal (abt. 1600) also built mechanical computing machines, but it is only recently, with Charles Babbage and Ada Lovelace's works in the early nineteenth century, that the real development of complex, programmable computing machines started. All along the twentieth century, the capabilities of such machines increased exponentially, in terms of raw power and computation possibilities, notably catalyzed by World War II and the cold war. Alan Turing made giant steps working on the Enigma, the coding machine German troops

used during the war, and shared his vision of what computers may be. In the 1950s, the electrical relays were replaced by vacuum tubes, then by transistors. At the beginning of the 1960s, integrated circuits opened so many possibilities that they attracted enough investment to create an economic bubble that led to an economic crash in 1962. The evolution of technology did not stop there, though. The IBM 704, one of the first supercomputers built in 1954, was capable of performing 40,000 operations per second. Today's consumer game consoles are able to perform almost 2 trillions of operations per second, and supercomputers get close to 500 trillion operations per second.

Beside the increase of the raw computation power that results from the evolution of the hardware, many algorithms were designed and improved to solve different problems. Monte Carlo Simulation (Metropolis and Ulam 1949), for example, was the first method to use the computers power to estimate, statistically, the value of a numerical parameter in a model by repeating a great number of experiments involving a random variable. It is still used today, in particular in physics and finance. Mathematical disciplines like operations research or graph theory were greatly influenced by the possibility to solve larger and larger problems with a computer and produced results that had an impact on other sciences. DNA sequences analysis, for example, relies on graph theory algorithms (Blazewicz et al. 2018) and the construction of phylogenetic trees uses optimization algorithms (Sardaraz et al. 2012).

Nevertheless, even though computers limits are constantly pushed away, the volume of data acquired by sensors grows even faster. New ways to perform computation had to be imagined to address the growing volume of data to be processed. Processing the data generated by colossal experimental facilities like the Large Hadron Collider (CERN, Geneva, Switzerland), or the National Astronomy and Ionosphere Center (Arecibo, Puerto Rico), requires the collaboration of thousands of computers across the planet. Each computer gets a small part of the data, performs the required calculation and sends back the result to the main processing unit which compiles the

results. This distributed approach, called *grid computing*, has started at a large scale in 1999 with the SETI@Home project at the origin of the Berkeley Open Infrastructure for Network Computing (BOINC) platform (Anderson 2004). It has made possible the confirmation of theoretical results such as the existence of Higgs field or gravitational waves. Today, huge datacenters are also used to perform such calculations in the *grid computing* approach and R&D is currently working on building Exascale supercomputers.

The Post-modern Prometheus

The computer is that complex machine capable to process numbers faster than any human and to extract information and create knowledge from unthinkable volumes of data. It became a source of inspiration for anticipation authors long before it reached the place it holds today.

On the philosophical level, the Age of Enlightenment allowed people to think openly that mankind may not be at the center of creation. This fall from grace opened the gates to a new world for authors and thinkers, who became entitled to imagine of a future where humans would be alone in charge of their destiny. Naturally, they imagined, long before it was technically possible, that we would be able to create androids, human-like robots. From "L'Ève Future" (*Future Eve*) published by Auguste de Villiers de L'Isle-Adam in 1886 to Isaac Asimov's *robots* series, starting with *Robbie* in 1940, androids became the technical version of Mary Shelley's *Frankenstein*. Considering the troubling accuracy of some of these works, it is easy to imagine that scientists who reached the key milestones in robotics were influenced, if not driven, by these visions. They, at least, come from the same desire to give birth to a creation in our own image.

When we look at robotics, for example, it is troubling to see how much progress has been made specifically to mimic the motion capabilities of animal and human bodies. Since Da Vinci's knight (1495), much effort has been necessary to give the capability to walk on two legs to a robot, which only happened in the 1990s, while robotic

arms were able to perform complex movements long before. Concerning interaction, synthetic voices keep getting better, thanks to the increased storage capacity that allows to embed a large number of samples. Natural language processing, the capability for a computer to understand a text expressed in a human language, has applications in automated translation, speech recognition, or text summarization (Chowdhary 2020). Back in 1966, ELIZA (Weizenbaum 1966) was the first chatbot able to mimic convincingly a Roger's person-centered therapy dialogue, paving the way to Siri, Nest, and Alexa.

These research efforts also have implications on the humans well-being. All the progress made to make a computer able to see, speak, understand language or walk are directly transferrable to compensate disabilities. We are now able to build exoskeletons to help paralyzed people, to make devices based on virtual or augmented reality to help the visually impaired, and to use vocal synthesis and brain-computer interfaces to replace speech for people suffering from neurodegenerative and neuromuscular sicknesses like Amyotrophic lateral sclerosis. Beyond creating a human-like robot, we are also making progress in human enhancement, coming closer to post-humanism (Hassan 1977).

Does innovation drive fiction or does fiction creates goals for innovation? When it comes to giving an answer to that question, it is easy to remember only the most visionary works and leave aside all the predictions that turned out to be wrong. Yet, this shows that this technological growth so profoundly changes society that everything seems possible, including dystopias like René Barjavel's novel *Ravages* (*Ashes, Ashes*, 1943), which was one of the first novel that identified the hazards behind technology. Since then such scenarios have now become part of the canon of fiction.

People Fear What They don't Understand

Arthur C. Clarke wrote the famous and over-quoted adage that “*Any sufficiently advanced*

technology is indistinguishable from magic.” (*Profiles of the Future*, 1973). Today, computers, networks and algorithms have become so complex that only experts have sufficient knowledge to truly understand what is behind the curtain and a fear of technological progress results from the difficulty people have to trust what they don't understand. Artificial intelligence, in particular, catalyzes all the fears, since it is particularly opaque, even for the professionals, and infiltrates in all aspects of our lives.

Artificial Intelligence also took advantage of the increase in computation power and the development of parallel and distributed computing. It is not a new idea, though, since Alan Turing already imagined that machines could be able to make decisions (Turing 1950). Artificial intelligence as a discipline was officially born in 1956 (McCarthy et al. 2006) and has known ups and downs over the years. Long quartered to recreational applications and demonstrations of power, it is only in 1997 that IBM's deep blue finally beat Chess champion Gary Kasparov and in 2015 that Alpha Go beat Fan Hui at Go, proving that, with sufficient power, computers can take series of decisions that form a strategy. There are many algorithms and techniques to make a machine learn to take decisions (Samuel 1959). That process often relies on a statistical learning process, in which an algorithm analyzes a huge number of situations and gradually learns which ones produce desirable outcomes and which ones should be avoided. The algorithm configures itself automatically based on experimental results, rather than being explicitly tuned by programmers. Algorithms therefore evolve to become black boxes and there is a natural concern that nobody is able evaluate what they actually do, since no human can make sense out of the thousands of parameters they use. There is now a promising research area that deals with *explainable artificial intelligence* (Došilović et al. 2018) to overcome these issues.

Artificial intelligence, however, needs huge databases of examples before it is able to learn something, that's why its evolution is concomitant to the rise of big data. The 2000s saw the birth of companies like Google or Facebook with a new

business model that relies on a more efficient advertisement, since it is targeted to the watcher. These companies rely on massive data collection to profile users, which only became possible with the rise in storage and processing capabilities. The era of data centers, cloud computing and big data, i.e., databases too huge to fit on a single computer or server, started with these big players and now concerns many virtual and physical services. Digital companies now all collect data to try to better understand their ecosystem and try to extract knowledge from that data with the help of statisticians, who evolved to data analysts. This trend is expected to further increase, thanks to the rise of the Internet of Things that has already started connecting all sorts of appliances to provide connected services.

We therefore have a connected world, in which commercial companies and institutions collect data continuously and are able to profile citizen. The use of these technologies is so widespread that our society and even our individual lives are now dependent on system so complex that it became frightening. That complexity also benefits malicious people who exploit cracks in the system to get access to valuable information, to various systems, or to destabilize organizations. In response, domains like cybersecurity and privacy have become incredibly active areas of research and development. These areas depend strongly on essential building blocks like cryptography, architectures, procedures and protocols, but are constantly evolving. When it comes to security, the world looks like a chessboard where defenders try to find and implement the good compromise between the protection of their assets and the usability by legitimate actors, while attackers try to find new strategies to get access to the information. For every new attack there needs to be a new or updated defense mechanism and that game has gone beyond the technical level. Today social engineering uses human manipulation, tricking users to disclose key information that can be used to get access to digital resources. It is an endless game in which the defender is almost certain to lose a battle sometimes. Since technology cannot provide any guarantee here, the problem has gone beyond the pure technical aspects

and more and more laws are written to define and enforce good practices. The European General Data Protection Regulation (GDPR), for example, limits the process of collecting data on European citizen, making the assumption that companies cannot disclose what they do not possess.

The Sky Is the Limit

Computers today therefore seem able to process and understand data, to make decisions, to interact with humans and have become the most complex industrial realization of mankind, with all the benefits and the dangers it creates. Advances in all the sub-fields of computer science seem to open an infinite number of possibilities whose only limit is our imagination. Nevertheless, there are limits to our capabilities. Computer Science, as a scientific discipline, can be divided between a branch that designs algorithms, finding new ways of solving problems like introduced above, and a theoretical branch that identifies possibilities and limits of technology. Some problems are inherently hard to solve, in the sense that they require a tremendous amount of computation to find the exact solution, despite their apparent simplicity. The traveling salesman problem (Applegate et al. 2007), for example, identified by Hamilton and Kirkman in the early nineteenth century, consists in finding an itinerary that passes through a list of cities once and only once, while traveling a minimal distance, given the inter-cities distances. Understanding the problem and finding “good” solutions seems intuitive. However, finding the *optimal* solution in any configuration requires comparing all possible paths, whose number grows exponentially.

That issue, called complexity, is a problem that concerns systems and algorithms scalability, i.e., their ability to find the solution for larger scenarios. On a machine that can process a billion of paths per second, solving a 20 cities problem would require more than 70 years of computation. Of course, parallel computing can help by dividing the exploration among multiple processors, but the problem is inherently complex, which means that it becomes much harder every time

its size grows. In that particular problem, like in many others, instead of chasing the optimum, we may be satisfied with a correct and fair approximation, which is much easier to achieve.

Several algorithms do use that complexity as a tamper-prevention mechanism. Ciphering, a part of cryptography, is based on that principle. A message is encoded into another message by an algorithm that ensures that it is impossible to come back to the original message without knowing the key used for the encoding. Decoding the message therefore requires trying every possible key, and the number of possibilities grows with the size of the key, up to the point where the only way to decode a message is to *know* the deciphering secret. The Blockchain technology, supporting the bitcoin currency, solely relies on that computational difficulty to ensure the integrity of a database of transactions distributed across multiple computers.

Research Today and Milestones Ahead

When looking at the evolution of computer science over the past decades, it is hard to find an aspect of our lives that has not been tainted by digitization. Science, communication, economy, health, public safety, education, art, marketing, assisted living, transportation, environment monitoring, etc. were all transformed by computers and algorithms. Research today continues in all areas to improve algorithms, to find new computation paradigms, to find new or better applications, to make it more accessible, safer, but also to understand and control its effect on human societies, on the way we interact together.

It sometimes feels like the research today is only incremental, then breakthrough concepts like deep learning or blockchain give a new breath to the community and to creative people who find new usages to these innovations. Many times, society felt like we had reached the end of innovation, and yet revolution after revolution, the future still seems full of promises. Nevertheless, there are some inherently hard challenges to overcome within computer science itself, but also in close disciplines like electronics or energy.

First, the increase in computation power has been driven by the miniaturization of the transistor. We are now close to a size of 8 nanometers below which quantum effects cannot be neglected anymore. We may be close to a limit here, but we may also learn how to deal with those effects, if not use them. Several technologies already use quantum effects. Solid State Drives are based on the tunnel effect for example and some research teams are working on quantum computers using quantum superposition and entanglement to make machines able to process a massive volume of data in parallel. Even if there are fundamental problems resulting from the quantum decoherence, the loss of quantic properties at a macroscopic scale, that technology should sooner or later provide a way to make a leap in computation, yet it remains limited to a particular set of problems.

More than a challenge, solving the issue of the energy is a necessity. Electronic devices need electrical power and processors are particularly hungry devices. Our whole society is built on information systems and communication networks. If energy were to become scarce, it would have a huge impact on the economy, but also on all aspects of our lives. There is, of course, research to find new sources of energy and to better use the ones we already have, but computer scientists themselves also try to reduce the energy consumption of the devices. Green computing and green networking have been active topics in the computer science field for more than a decade and try to look at complexity in a different way: how to build better algorithms, which require less energy to find a suitable solution. On the hardware level, asynchronous circuits could be a game changer, since a huge amount of energy is consumed by the existence of a clock signal and its propagation across the millions of transistors that compose a processor.

Conclusion

There is no possible denial that computer science has changed society since it reached the everybody's pocket. Behind that technology lies

the possibility to better understand our world and societies, but also to reshape them. Worldwide challenges like poverty, environment or education could be impossible to solve without the assistance of these devices. Nevertheless, computer science is a tool, which open possibilities in its applications, and solutions will not come without a will to go in the proper direction. Like all fundamental advances, it is also a two-sided coin, which, aside from the unlikely dystopian scenarios, bears the potential of increasing our dependence on energy and accelerate our depletion of non-renewable resources.

Concept Formation

Valentina Fernández Guzmán, Ingrid González-Palta and Antonia Sutil Larrain
Universidad Alberto Hurtado, Santiago, Chile

Abstract

In this chapter, we argue for *the possible*, as that which is opened through the juxtaposition of different perspectives in the unfolding of language, as both the main field of, and transformed by, concepts. We follow Vygotsky's (1934/1987) theory of concept formation to understand concepts not as mental and neutral representations but as different and related perspectives that unfold through specific ways of speaking and thinking in a horizon of positioned meanings (Bakhtin, 1981). The particular case of argumentation as a discursive practice in forming the possible, and, through it, forming concepts, is discussed. The political and social implications of this understanding are addressed.

Keywords

Concept formation · The possible · Sociocultural theory · Language

Introduction

Although the notion of *the possible* has been addressed throughout philosophical thought, it has rarely been explicitly discussed in the field of psychology. This limited attention is surprising, given psychology's concern for psychological processes embedded in a diverse and cultural world (see Glăveanu, 2020). According to Glăveanu (2021), psychology pays more attention to the limits and constraints in human psychological potential than it does to processes

and consequences. Despite this, *the possibility* can be traced in various psychological concepts such as imagination, creativity, and counterfactual thinking, among others (Glăveanu, 2021). In fact, sociocultural theory is one of the perspectives that can illuminate the notion of *the possible* most productively because it assumes that the psychological mind arises *in* and *through* a perspectival world as a constitutive element. In this sense, it is not isolated individuals who interact with cultural diversity. The individuals themselves are constituted by the social world in which they participate. From a sociocultural perspective, authors such as Dewey (1966), Mead (1934), Vygotsky (1934/1987), and Bakhtin (1981), among others, have positioned the idea of otherness as a fundamental notion of human development insofar as it originates in the movement of response to multiple perspectives. In this way, sociocultural assumptions are a crucial starting point for understanding *the possible*.

According to Glăveanu (2020), *the possible* is a relational phenomenon embedded within self–other, person–world relations. Specifically, *possibilities* find their foundation in differences, particularly in the difference between perspectives. From this viewpoint, what would open the entrance to the possible in our existence would be the relationship with more than one perspective. This sociocultural perspective understands the possible not as something contrary to what is actually “real” but as an action that shapes – through a perspectival world – the individual’s experience in the real. In this sense, the antithesis of *the possible* would be the denial of multiple perspectives rather than the real experience itself (see Glăveanu, 2020).

This way of understanding the notion of *the possible*, not as the opposite of the actual but as the recognition of a perspectival world, can illuminate one of the essential psychological activities for human development: concept formation. Therefore, this chapter seeks to answer the question: What place does *the possible* occupy in relation to concept formation? To answer this question, it is essential to understand what is proposed by Vygotsky (1934/1987) as an alternative

explanation to the traditional way of understanding concepts as mental representations. It is argued that *the possible* occupies a central role in concept formation if it is assumed that concepts are not predefined mental entities but social activities unfolding through speech.

Vygotskian Perspective of Verbal Thinking

Thinking and Speech as Intermingled Processes

Vygotsky (1934/1987) argues that the fundamental difference between the non-human and the human is that, in the latter, verbal thinking mediates psychological functions. This, however, does not occur for biological reasons; it occurs during human ontogenetic activity, and Vygotsky argues that language learning plays a crucial role. However, why is language crucial for psychological development in a person’s ontogeny?

According to our reading of Vygotsky (1934/1987), children are progressively immersed in a verbally performed world. Experiences are not randomly or idiosyncratically organized but generalized through a language that is already there, before children are born. Every use of language implies a particular way of generalizing a particular stream of experience, that is, of treating it as structured in a relative, repeatable way. When they start to perform language agentically, children start to generalize through those words; that is, they start to co-generalize with virtual others that have populated those words before. In other words, children with language begin to think, to generalize, as other speakers populating those words have done before. Language performance then opens up the encounter, the interdependence of I–other perspectives: that of many speakers performing that form of language before the child, but also the child’s own unrepeatable ways of generalizing with the same words. Language performance, therefore, not only implies a sequential chain of responses but also produces the juxtaposition in the same stream of experience of different perspectives occurring and co-influencing their formation at the same time.

Moreover, through the child's verbal performance of alien words, and its appropriation, these juxtaposed and co-influencing ways of thinking progressively become an integral part of how the child thinks. Language performance is not only for communication but also for collaborating psychologically, and, through language, social and initially external forms of collaboration become part of the individual functioning: "Each higher form of behaviour enters the scene twice in its development – first as a collective form of behaviour, as an inter-psychological function, then as an intra-psychological function, as a certain way of behaving [...] into the practice of personal behaviour" (Vygotsky 1997, p. 95). This process, which Vygotsky refers to as internalization, is central to children's development.

Vygotsky's Theory of Concept Formation (1934/1987)

Vygotsky (1934/1987) describes, in Chapters 5 and 6 of *Thinking and Speech*, his theory of concept formation. Specifically, Vygotsky understands concepts (or word meanings) as generalizations, that is, "operations in which a particular and unique event is treated as a class of events" (Larrain, 2017, p. 3). Concepts then are actions or movements (they change), something people do when they think: people do not generalize in the same way through ontogeny. The way of generalizing change is prompted by the different verbally organized social activities in which people participate during their lives. Vygotsky considers the period that goes between language learning and adolescence to be key to concept development.

To say that concepts are actions and not entities, and that these actions change through development, implies understanding concepts in a way that is radically different from the traditional way. Concepts have traditionally been understood in psychology as mental representations associated with cognitive categorization processes, mental categories created from similar characteristics (Braisby & Gellatly, 2012), and as organizing information and representing the world through an algorithmic or non-natural language. This traditional way of understanding concepts has

encountered various difficulties, such as cases that cannot be logically categorized (borderline cases). Based on this explanation, difficulties or disagreements are interpreted as a lack of knowledge, which can be resolved by consulting official knowledge. In this sense, concepts are already defined (based on shared properties or specialized knowledge). Another problem with traditional understandings of concepts is that they do not account for the particular ways in which people conceptualize and think about concepts. For instance, Medin et al. (1997) observed how participants with different occupations (e.g., maintenance workers, landscapers, and taxonomists) grouped trees into taxonomies with marked differences. In other words, when these people defined the same concept (tree), the ways of thinking about it were significantly different. A third problem related to understanding concepts as definitions or established knowledge is how such a view limits the possibilities for conceiving the process of concept development: concepts would be incorporated by the minds of individuals only as a matter of accessing information.

On the contrary, from the perspective that is adopted here, a concept is not a dictionary definition but a movement, an act of generalization. Concepts are movements of thinking through people's experience in generalized ways. Vygotsky (1934/ 1987) argues for different structures of generalization emerging through development. When children start to talk and use a certain word, they start generalizing with that word in an idiosyncratic, unstable, perceptual, and syncretic way. However, even with these characteristics, these generalizations are not completely individual but rather socially influenced, because children encounter words and their performance in already organized social activities that direct their own generalizations. Therefore, there are gaps between adults and children using the same words, and at the beginning, these gaps are evident. However, when generalizing with words, generalizations necessarily occur through a social and dialogical dynamic in which at least two perspectives co-occur in the same stream of life. That is why, in persisting in the social use of language, children's generalizations undergo a

process of constant transformation: from contextual and idiosyncratic generalizations (complexes or spontaneous concepts), children's thought moves to conventional and systematic ways of generalizing (scientific or "true" concepts). Thus, it is evident that, for Vygotsky, the concepts are not the product of previous mental processes of categorization; rather, concepts are developed continuously whenever language is used.

It is interesting to note that the last phase of the development of complexes (or spontaneous concepts), according to our reading of the author, called pseudo-concepts, are children's generalizations that apparently coincide with adults' generalizations but still qualitatively differ. This observation is relevant because it shows that, for Vygotsky (1934/1987), the use of the words does not coincide with concepts: one can use words in a similar way but still generalize with those words in different ways. These pseudo-concepts are eventually qualitatively transformed into "scientific concepts" when children, through the use of a certain type of language, form a system of meanings; that is, they generalize through the systematic and conventional relations between meanings. The system of meanings is basically a relational verbal web that is formed and which involves different types of relation: hierarchical relationships (longitude) and relationships of commonality (latitude). Therefore, systematic social experiences such as instruction, and their particular ways of performing language, prompt the development of this structure that organizes generalizations in adult life. Hereafter, generalization becomes more decontextualized and verbally dependent, and more conventional and repeatable. This does not mean that at this stage words coincide with concepts, because, even with the same words, different paths of generalizations (different relationships) can be performed. Moreover, as generalizations unfold through a system, different alternative generalizations are possible and are systematically related to, and interdependent on, one another. This diversity of possible juxtaposed paths unfolds in the language in the reconstruction of the concept. According to Larrain et al.

(2019), "scientific concepts can be thought of as occurring through multiple equivalent conceptual paths emerging when speakers only have at their disposition more than one way to equivalently think of a word (a semantic system)" (p. 458). This relational web allows people to make their own generalizations; that is, it opens the door to a certain type of meta-thinking.

The Role of the Possible in Concept Formation

From Vygotsky (1934/1987), it can be hypothesized that *the possible*, as the encountering of different perspectives or alternative ways of seeing reality (different angles), enters the scene for the first time when the *other's way of doing or thinking* appears to the child. This happens only because the child starts using a language that they find is already there (Bakhtin, 1981), laden with intonations, positionings, ways of generalizing, or ways of affecting and being affected by. Moreover, the possible is not only discursively created but also conceptually structured and transformed. In saying this, we mean that the possible, as the juxtaposition of different perspectives, is not there as static images but as a creative activity through which, and in which, concepts play an important role, regardless of their stage of development. Perspectives always have a conceptual nature, in the sense that in a way they involve specific ways of generalizing. But they do it because they emerge in a collaborative performance of language, which in itself opens up whole fields of perspectives sedimented in the linguistic forms that are singularly performed. As such, the possible involves not only generalizations but also generalizations occurring in a dialogical relation of interdependence that change and vary along development. While, at the beginning of development, the possible is structured as social generalizations in dialogical relationships that influence one another in a syncretic and unrepeatable way, in adolescence the possible is transformed by the conventional web of generalizations knitted throughout instructional social

interactions, which refer to one another in repeatable ways. Consequently, the possible develops micro and ontogenetically.

A Vygotskian perspective is coherent with the possible insofar as the concepts are conceived as movements of co-affecting and co-occurring thinking paths establishing dialogical systematic relationships of influence between one another (and not as neutral, unique, and immutable entities). In other words, concepts are more than information storage; they are acts of verbal articulation (movement) of diverse positions. This idea gives *the possible* a fundamental place in concepts. Indeed, a concept could not be conceived without *the possibility* because the process itself implies paths of meaning. Each movement of thought is illuminated through the light of possible meanings and perspectives.

For this reason, *the possibility* not only determines what a concept could become but also determines what it is. It is impossible to understand concepts without acknowledging that there are alternatives. Thus, concepts exist not as crystallized products but as articulations of possibilities. The possibility is the background of a concept as different trajectories that are potentially passable depending on the use of the language.

This Vygotskian conceptualization of understanding concepts considering *the possible* (thought acts of potentially passable meanings) resonates with Bakhtin's (1981) theory of language. For Bakhtin, language is understood not as an abstract language system but as a discursive practice that organizes social life. Bakhtin asserts that every utterance is dialogical and has a response structure, as they always anticipate and respond to other utterances. From this perspective, language lives in a chain of past, future, real, or imagined positions that sediment social life. Utterance always emerges in a virtual field of evaluative/affective positions supported and produced by social and cultural life (Haye & Larraín, 2011). From there, any act of understanding is mediated by a world of perspectives in tension. In other words, acts of understanding are produced by a world of possible voices (Haye & Larraín, 2018).

Thus, for Bakhtin (1981), the emergence of each discourse takes place in a field of contradictory, virtual, past, real, and imagined positions, value judgments, and points of view. Thus, the nature of *the possible* in language can be understood as the field of voices in tension. In other words, the virtual field gives meaning to all that exists (e.g., interpretations, alternative possibilities, a sense of understanding). In this field, intellectual thinking for concept formation would not occur in a cognitive network of neutral statements. Language as a field of diverse evaluative positions implies understanding that the formation of concepts is not a rational activity dehydrated from social, affective, and political positions.

Considering *the possible* (from a Vygotskian and Bakhtinian approach), concepts are not neutral products but evaluative ways of moving that articulate a social field available in a given time and space.

In summary, when people begin to perform language, a horizon of possible meanings and perspectives begins to open up and materialize through these uses, because the other offers a specific way of seeing and interpreting the world through historically and culturally situated uses of language. Consequently, language practices materialize cultural and social possibilities (i.e., a world of perspectives). In this sense, the place of possibility resides in the ways of speaking and thinking, embedded in the cultural practices in which one participates. In other words, through language, the possibility is semiotically mediated by communities' cultural meanings.

Argumentation as a Type of Language Performance That Prompts the Conceptual Aspect of the Possible

So far, different types of language use have been referred to as key to concept formation and the creation of the possible. In this section, a particular example is explored: the case of argumentation as a macro-speech structure. Empirical evidence shows that argumentation could be a powerful practice for concept formation and transformation (Asterhan & Schwarz, 2016; Asterhan &

Babichenko, 2015; Larraín et al., 2021). Argumentation is traditionally conceived of as the socio-discursive practice in which one or more speakers deal with a controversial issue through the critical examination of alternative perspectives, thereby assessing the acceptability of controversial ideas (Perelman and Olbrechts-Tyteca 1969; Toulmin 1958).

According to Leitão (2000), when people raise and construct an argument, they conceptualize it in a particular way, justifying a specific position. When a counter-argument emerges (either from someone else or from within oneself, as in internal speech), new possibilities for alternate meanings (unaccepted or contradictory ideas) open up. Eventually, these new possibilities can be internalized in a more complex and comprehensive conceptualization. In fact, according to Reznitskaya and Wilkinson (2017), a good argument can be defined as a position that not only justifies but also articulates alternative paths.

When arguing and encountering alternative and contradictory ways of conceptualizing the same event, not only does one become aware of different possible trajectories that support a position but one is also able to articulate and respond to this field of contradictory positions (Bakhtin, 1981). From here, a good argument would be a particular articulation of possibilities and alternatives related through contradiction, which in turn would broaden the understanding of something (González-Palta & Larraín, 2021). Consequently, when arguing, what is possible is updated to respond to a demand for the articulation of meaning.

From this perspective, the effort to articulate the field of *the possible* is the reconstruction of the virtual world from particular modes. By arguing, *the possible* is shaped, its network updated to respond to a demand for meaning. If one defines a concept by illuminating only one possible path (denying perspectives), the concept's contradictory and unaccepted paths are invisible. The argumentative practice, understood as a discussion of diverse and contradictory ideas, brings to the fore implicit paths not travelled by a concept, demanding the articulation of the various trajectories of *the possible*.

Therefore, the challenge of learning and understanding any concept in instructional contexts, especially concepts that involve a complex and contradictory path (at different educational levels), calls for their exploration and articulation from a framework of what is possible, precisely because this responds to the nature of concept formation. For example, the role of argumentative questions gives rise to imagining new articulations and invites one to go through alternative paths (even when they are incorrect or not accepted), which fulfil fundamental processes in understanding and reconstructing concepts.

On the contrary, understanding concepts without an idea of *the possible* would only render an already accepted concept path, a unique definition. Such unidirectional understanding of concept formation is what is usually observed in instructional spaces. Similarly, when dialogues only add instead of discussing reasons, it is not possible to go through a field of position-meanings because paths are only travelled in one direction. Instead, the discussion of different and contradictory ideas (through arguments and counter-arguments, imagining opposing scenarios, etc.) allows a complex framework to be traversed.

In other words, true concepts are nothing more than the articulation of possible paths (alternative meaning trajectories). When responding, anticipating, and critically evaluating alternative paths, a concept is presented facing *the possible* (a process of articulating among other possibilities).

From this perspective, argumentation as an act of anticipation demands that one imagine a field of possibilities: an effort is made to produce *the possible* through functional uses of language that sustain said production (Larraín, 2017). In other words, participating in an argumentative dialogue would promote the emergence of novelty in the formation of concepts. However, as Vygotsky would argue, language practices are historical, leading novelty to emerge in the particular recreation of a horizon of meanings.

In this sense, the functional structure of argumentative language directs thought, demanding an effort to imagine – not only to produce and go through possible alternatives but also to articulate and organize thoughts. An effort is made to

produce *the possible*: to make implicit perspectives visible; to articulate thoughts in unique and specific ways. In short, the place of *the possible* in language (particularly of argumentative language) is critical not only for the development of verbal thought and concept formation but also as the place to imagine and produce a horizon of possible, contradictory, and potentially passable meanings.

Conclusion

The goal of this chapter was to understand the place of *the possible* in concept formation. Acknowledging that possibilities and perspectives have a role in concept formation, this chapter set out to explain theoretically how and why this occurs. Rather than proposing a new theory of concept formation, the idea was to address *the possible*, from a sociocultural theory (Bakhtin, 1981; Vygotsky, 1934/ 1987), as a way to understand concept formation.

Specifically, this chapter argues that (i) *the possible* emerges only with the use of language (collaborative and historical performative language); (ii) *the possible* emerges in the dialogical nature of concepts given their dependence on language (field of perspectives knitted throughout social interactions); and (iii) *the possible* is conceptually structured and transformed.

Therefore, it is important to recognize that what is called *the possible*, from a Vygotskian perspective, is necessarily discursively constituted and conceptually mediated. Concepts such as acts of generalization or historical and cultural ways of thinking will cross any human experience, even with understanding their role in imagination and affect (or any other psychological process). This is explicit in Vygotsky even when the idea of personality is discussed in *On Psychological Systems* (1997). Consequently, the conceptually organized and dialogically constituted of *the possible* runs through intellectual, artistic, and emotional (material-vivid) experience. For example, the possibilities of being affected when appreciating a painting are conceptually mediated and discursively constituted: the affected experience is materialized by a

language performed by historical and cultural forms through social interaction. This idea of *the possible* is supported by an assumption about language that is radically different from the traditional. It is about considering the language of psychology as an embodied activity, as a performance between socioculturally situated individuals (see Bertau, 2014). Moreover, the dialogical and performative notion of concepts implies that *the possible* is in motion and develops historically. What is possible in concept formation would materialize in language performance, across human development, and would be mediated by cultural and historical practices.

Finally, there is the question of why it is relevant to specify, theoretically, the role of *the possible* in concept formation. A traditional understanding of concepts as fixed entities or products, not as a social activity (a process that gives rise to *the possible*), would have consequences from an educational, social, and political point of view. Understanding concepts as products, or from the impossible (see Glăveanu, 2020), would imply formulating an explanation that would limit the understanding of human development in crucial aspects for concept formation. This is because such an approach makes the transforming and material role played by specific uses of language invisible to learning processes. In other words, concept formation would not occur if specific language uses could not trigger, illuminate, and formulate possible, contradictory, or unaccepted alternatives (the field of *the possible* in concepts). The traditional view of the meaning of concepts, as abstract and neutral representations, is problematic. This is because it makes it difficult to imagine more precise learning devices that properly respond to human thought processes and the educational demands of an increasingly culturally diverse and complex society. Also, a traditional view neutralizes and dehydrates the intellectual activity involved in a socially situated field of thought (Bakhtin, 1981). Understanding conceptualization by denying *the possible* (possibility of speech perspectives) limits educational spaces for thought. This closes down the possibility

for collaborative discussions and deliberations on the basis of different perspectives, therefore limiting the possibility to arrive at more just and creative solutions to the multiple challenges, crises, injustices, and complex transformations that today's society demands from us (Dewey, 1966).

Constructive Memory

Brady Wagoner

Centre for Cultural Psychology, Department of
Communication and Psychology, Aalborg
University, Aalborg, Denmark

Abstract

Constructive or reconstructive memory describes the process by which we update our memories in light of new experiences, situations, and challenges. Although the literature on the topic is far too vast to cover in a short review, we can identify two broad research approaches to it. One conceives “constructive” as a vice of memory and aims to identify the factors that increase “errors” and “inaccuracies” in memory. In contrast, for the other “constructive” is a virtue in that it is indicative of the creativity and adaptability of memory to meet a changing world and is closely connected to imagination. The former approach tends to employ an experimental methodology, whereas the latter tends to study so-called “natural” contexts of remembering. This chapter begins with a reflection on the inherent ambiguity of the past and the dilemmas and possibilities this creates in human life. It proceeds to shed further light on the two meanings of construction through a review of some key studies. This is followed by an explanation of the schema concept, which is widely used in both research approaches. The chapter then explores the long discussed relationship between imagination and memory. It concludes with a look at the intertwining between individual and collective forces in remembering from the perspective of socio-cultural psychology.

Schema · Imagination · Inaccuracy ·
Sociocultural

Introduction

The past is a mysterious thing. Events happen to us but our temporal distance from them leaves many ambiguities when we attempt to recall and interpret the past. We tend to mix details from different events and shape our accounts to fit current goals, which also can create important divergences in the way people tell stories about the “same” happenings – what is often called the Rashomon effect, after Kurosawa’s famous film by that title. Both in our own uncertainties about the past and in the conflict of testimony, memory creates a field of possibility rather than something to be taken at face-value, settled once and for all. Some psychologists have even argued that entire events might be unwittingly confabulated – Loftus and Ketcham (1994), for example, have said a well-meaning but suggestive therapist can implant memories of child sexual abuse in their adult patients. Even in the event that we take our memories as faithful accounts of the past, we might still interrogate them for what *might* have happened had something been different (i.e., counterfactual thinking about the past). From an approach quite different to Loftus and her colleagues, Brown and Reavey (2015) have pointed to how survivors of child sexual abuse will often question their own agency in the situation – “could I have acted differently?” They argue that keeping such ambiguities alive can be productive for developing the self and opening up action possibilities in the present. In short, we can say that possibility is a key part of constructive memory in that the past is never fully settled, which ensures its functional value within the ever-changing environment. Most contemporary theories of memory would agree on this point but there nonetheless exists opposing research approaches with differing assumptions to the topic.

What Makes Memory Constructive?

When Ebbinghaus (1885/ 1913) inaugurated the psychology of memory he conceived it using the metaphor of inscription: Sensations are impressed

on our mind leaving traces which can later be recalled. Although his new experimental method of remembering nonsense syllables was an innovation, conceptually he was directly in line with Plato and Aristotle's theories a millennia and a half earlier. In the early twentieth century, thinkers began to question the understanding of memory as a *substance* or *thing* in the mind and began to see it instead as an *activity* or *process* taking place between a person and their world. This perspective is clear in the process philosopher Henri Bergson's (1911) *Matter and Memory*, sociologist Maurice Halbwachs (1925/ 1992) *On Collective Memory*, and psychologist Frederic Bartlett's (1932) book *Remembering: A study in experimental and social psychology*, but the idea can be traced back much earlier to Lotze's notion of the "activity of memory." In all cases, it is because the past is mobilized to deal with current actions that it is flexibly adapted and as such is highly functional for human life. As Bartlett (1932) put it, "The external environment... partially changes and in part persists, so that it demands a variable adjustment, yet never permits an entirely new start" (p. 224).

Whereas Halbwachs (1992) analyzed how different collectives, such as the family, religious group or social class, organize the memory of their members, Bartlett (1932) began his study by having participants repeatedly recall foreign folk-stories, after 15 min, a week, several months and even years later. His choice of unfamiliar stories was deliberate in that he wanted to foreground how the stories are transformed in memory when they are interpreted through a different set of conventions. Most famously when participants recalled a Native American story called *War of the Ghosts* they tended to change "canoes" to "boats," "hunting seals" to "fishing," add details to create a smoother narrative, and rationalize away its puzzling and supernatural elements. Wagoner and Gillespie (2014) show that when people do this memory task, they tend to make numerous suggestions about what might have been in the story and then evaluate them on how best they fit and how familiar they feel. In this way, we construct memories by gradually

approximating an account from a set of *self- or other-generated possibilities*. These reflections might be based on fleeting imagery, embodied metaphors, narrative expectations, etc., which are then woven together in an integrated account. For Bartlett (1932), this is what gave constructive remembering its hesitant and erratic character, in the process of putting together these fragmented pieces.

Since the 1960s, psychologists have tended to interpret these findings to mean that memory is always highly unreliable. Researchers operationalize the notion of constructive by counting up errors and inaccuracies in recall when compared to the original material. In this approach, literal recall is considered to be the highest goal and any deviation from it a vice of memory (Wagoner 2017). In contrast, for Bartlett and many earlier thinkers, memory's constructive character was its virtue, in that it highlighted creativity and flexible adaption of experience in a changing world. A clear milestone in this shift of focus can be seen Gauld and Stephenson's (1967) study which aimed to show that the "reconstructive" process identified by Bartlett was the result of his loose task instructions rather than something inherent to memory. As such, they told participants to recall *War of the Ghosts* "fact for fact" immediately after reading the story and counted the number of extreme deviations from the original that they called "errors." They thus intended to do the exact opposite of Bartlett by creating a situation very different from the way we remember in everyday life. The assumption is that one could isolate a pure faculty of memory, uncontaminated by other influences and guesswork of the participant – thus, treating memory as a thing rather than an activity. While they did find fewer errors when compared to Bartlett's studies, more recent research has showed that this effect disappears after a week, so that there is no difference between strict and loose task instructions (Bergman and Roediger 1999).

Even within the more limited understanding of constructive, there has been a shift from away from an Ebbinghausian focus on how much is remembered (i.e., quantity oriented) to an

exploration of the *correspondence* between original and recall (i.e., quality oriented) (Koriat and Goldsmith 1996). However, the two are often combined in research, when quantity of information and distortions to it are both analyzed. The focus on errors and distortions open up for the investigation of “the possible” but only in the negative and limited sense of being deviations from the truth, and as such are considered potentially dangerous and best avoided. This has obvious utility in contexts such as a court of law where accurate testimony is essential, but should not be the ultimate standard for evaluating memory across social contexts (Brown and Reavey 2018). More often than not, recall functions more to orient and motivate action, bond with other people, and construct personal and social identities than to create literal representations of the past. The notion of constructive remembering as a flexible adaptation thus holds much more promise for investigation into *the possible*, in that reflection on the ambiguous past becomes a source of invention in the present, opening up new pathways towards the future. This was in fact also the view of the medieval craft of memory (Carruthers 2008), which is why *invention* and *inventory* share the same root: to invent one had to have developed an organized and flexible memory (see section “[Imagination and Memory](#)”).

The Concept of Schema

If memory is constructive then the idea that experiences are stored as static impressions or traces in the mind/brain until they are recalled is deeply inadequate. Instead, experience comes into being and is remembered in relation to other experiences and the context one finds oneself. People accumulate experiences into an active and developing pattern which creates the organized setting for new encounters with the world. Bartlett (1932) called this background of pattern making activity “schema,” which has become the preferred term for memory researchers since Neisser’s (1967) employed it as a key concept for the new sub-discipline of *cognitive psychology*. However, while Bartlett remained wedded to a bio-

functional approach to living organisms that must act in a changing environment, Neisser and cognitive psychology more generally adopted a mechanical computer metaphor: Schema were said to be the program instructions for coding information put into the system from the outside. For example, we tend to remember schema consistent items of a graduate student’s room, such desk, calendar, pencils, books, etc., at a much higher rate than inconsistent items, and where such consistent items are not present we often fill in default values in memory (Brewer and Treyns 1981). This is of course not wholly wrong but misses some other important aspects of memory.

The early cognitive approach can be criticized for (1) cutting the person off from the world, (2) turning the mind into a series of storage compartments, and (3) neglecting questions about the origin and development of schema (Wagoner 2013). In his later work *Cognition and Reality*, Neisser (1976) himself introduced a more ecological approach to solve these problems, having been persuaded by J.J. Gibson of the inadequacies of the earlier formulation. Schema then became a way of picking up “invariances” in the environment for both perceiving and remembering. While first developed by Gibson (1966) to show that perception involves picking out invariant information within ones optical flow, Neisser combined the notion with schema to show how memory is organized into “repisodes,” which pick out invariant information found across repeated “episodes.” In his famous study of John Deans’s memory for conversations with Nixon during the Watergate scandal, Neisser (1982) showed that while Dean’s description of details for particular episodes was often in error, when compared to the recordings later uncovered, the testimony was faithful to shared characteristics of multiple episodes or a “repisode” of the conversations.

In this account, schema becomes a background condition for the ongoing *attunement* to the environment, rather than a static structure with nodes for filling in discrete values like a computer program might do. Bransford et al. (1977) used the metaphor of “setting the stage” to understand the

more dynamic conception of schema: “a major role of past experience is to provide ‘boundary constraints’ that *set the stage* for articulating the uniqueness as well as sameness of information” (p. 434, emphasis in original). For example, familiarity with driving a pickup will set the stage for experiencing the smoothness of a car’s ride. Thus, the most basic level of schema is a kind of body memory that allows us seamlessly act in a world that has both characteristics that persist and change. Bartlett himself became interested and began investigating the notion of *skilled performance* after having developed the schema concept. According to him, skill is marked by “complex, coordinated and accurately timed activities. The stimuli in response to which activities are set up are neither simple nor do they usually fall into a fixed succession. They have the character of a field, or a pattern, which become highly organized” (Bartlett 1941, p. 718). In contrast to fixed habits, the notion of skill is linked to a flexible opening of possibilities. This is aptly shown in Glaveanu’s (2012) study of creativity as mastery in the context of artistic Easter Egg decoration: one must develop basic habits of action in order to open up the possibility of high-level innovation and improvisation. Parallel mechanisms of improvisation can be seen at the level of memory skill in, for example, waiters and professional mnemonists (Ericsson and Polson 1988).

Imagination and Memory

Imagination and memory tend to be thought of as belonging to opposite ends of the conceptual spectrum in everyday language and psychology today: one dealing with the free play of mind and the other storage of sensory impressions. However, this was not always the case, as the shared root of invention and inventory mentioned above reveals (Glaveanu and Wagoner 2016). According to the ancient art of memory (Yates 1966), for example, mastering memory required imagination and was necessary for innovation. In its earliest formulation to the art of memory required that one create images of the things one wanted to

remembered and situate them within a familiar place in one’s imagination, to create a spatially organized system of memory. The images should be symbolic and bizarre in order to maximumly evoke memory. When a statesman wanted to deliver a speech they walked through the familiar place in their mind and read off the images representing the themes they wanted to cover. Thus, memory here was not focused on remembering isolated facts or incidents, as we tend to think of today, but rather as a system of organized ideas that could be recombined to generate novelities and was adaptable to the audience and situation. This is why the greatest genius of early medieval times, Saint Augustine, was at that time praised for his “memory” first and foremost, whereas we today would focus on the “creativity” of genius (Carruthers 2008). This says more about our shifting values and conceptualizations than a change in the psychology of invention.

Memory and imagination only went their separate ways during the enlightenment, where traditional truths were to be scrutinized by reason and method. The status of memory was already lowered by Descartes, who saw it as bound up with the bias and contingencies of the body. According to him, only a rigorous scientific method could guarantee truth. Similarly, in the empiricist camp Hume relegated memory to a faded form of perception, a copy of sensation in the form of a mental image. Imagination was then the faculty that mixes up these images to create fanciful things and distortions of reality, like imaginary beings constructed by putting together different animal parts. Such a view is in many ways present in much of the 20th experimental psychology of memory, as can be clearly seen in Gauld and Stephenson’s (1967) study discussed above. Memory under this conception became either a rather limited or suspect mental faculty.

Its suspect status has been a major focus within the domain of eyewitness testimony, especially as pioneered by Loftus and colleagues’ work on the “misinformation effect” (for a review see Loftus 2005). In these studies, participants are shown a film of a fast-moving event (such as a car accident) and then asked a series of questions about it, some of which suggest things that were not in

the film (such as “broken glass” or a “barn”). Later participants are more likely to remember these suggested but not originally present items when recalling the event. The assumption is that social influences or suggestions contaminate individual memory. This notion of suggestion itself comes from the late nineteenth century, where it was shown that hypnosis could implant memories through this technique (Motzkau 2009). The problem is that from a developmental perspective human memory seems to rely on a social and cultural framework, in which either someone else makes suggestions to us or we learn to make them to ourselves (i.e., autosuggestion). As Halbwachs (1925/1992) put it: “It is in society that people normally acquire their memories. It is also in society that they recall, recognize, and localize their memories” (p. 38).

From a Bartlettian constructive perspective, we could argue that essentially all high-level memory involves suggestion, either by others or by oneself. Having expectations about what normally takes place already shapes perception and recall of things (see section on “[The Concept of Schema](#)” above). Fully developed human memory effectively involves internalizing and habituating narratives of everyday events, like visiting a restaurant. As described above, Bartlett (1932) had in this way already brought imagination and memory together, arguing that “remembering is an imaginative reconstruction.” More recent work in philosophy and neuroscience has argued that both are forms of “mental time travel” (Perrin and Michaelian 2017) that allow us to break out of the here-and-now situation, so as to return to it with other perspectives, thus enlarging the realm of possibilities for action (see also Zittoun and Gillespie 2018). Even from a neurological level, the two cannot be clearly distinguished: Schachter et al. (2007) have demonstrated that the same regions of the brain are active in remembering one’s last birthday and imagining one’s next birthday. According to them, both are functional in prospectively anticipating the future and thereby facilitating action in the present. They also open up a space for bringing together experiences from different contexts, which is the primary characteristic of analogical thinking.

Constructivism

Eduardo Martí

Facultat de Psicologia, Universitat de Barcelona, Barcelona, Spain

Abstract

Constructivism, when applied to the theory of knowledge, it is a theoretical perspective, postulating that knowledge is the result of a constructive process of the subject. Piaget is the clearest reference when dealing with constructivism. In this section the main ideas of Piaget's constructivism are analyzed in the domain of epistemology and psychology. Piaget's research on the creation of new possibilities is also mentioned. Finally, Piaget's constructivism is contrasted with Vygotskian co-constructivism.

Keywords

Cognition · Constructivism · Development · Epistemology · Piaget · Psychology

The polysemy of the term “constructivism” requires clarification. When applied to art, “constructivism” refers to an artistic style initiated in Russia at the beginning of the twentieth century. When applied to the theory of knowledge, it is a theoretical perspective, postulating that knowledge is the result of a constructive process of the subject. This section will expand on the second meaning. The constructivist perspective can be applied to many domains of knowledge: mathematics, psychotherapy, sociology, biology, theology, epistemology, psychology, and pedagogy. When applied to sociology and politics, the term used is usually “constructionism” (see section “Constructionism”). In this section, however, the case of psychology will be addressed and, within psychology, the work of Piaget will be the focus (see section “Piaget”).

The choice of Piaget is not at random. In psychology, Piaget is the clearest reference when dealing with the topic of constructivism. The importance of Piaget may be surprising if we consider that the term “constructivism” appears only late in his work (Piaget 1980). However, his assertion that knowledge is the result of a slow process of construction is a constant throughout Piaget's work. For example, one of his first major works is entitled, *The Construction of Reality in the Child* (Piaget 1954/1937). The idea that knowledge is the result of construction is, therefore, a central idea of Piaget's theoretical perspective. He posed this question within the domain of epistemology.

Piagetian Constructivism in Epistemology

Piaget's constructivism is inseparable from its epistemological positioning. This positioning gives meaning to and bases his work in psychology. As with any statement related to the knowledge process, two entities are required: a subject

(the person who knows) and an object (the external reality, or object of knowledge). Piaget’s epistemological approach starts from his analysis of the possible relationships between both of these entities. He distinguishes three possibilities: the primacy of the object, the primacy of the subject, and the impossibility of dissociating them (known as “indissociation”). Piaget then adds a second dimension of analysis, which is related to the origin and formation of knowledge. According to this dimension, there are solutions that postulate the development of knowledge (or as Piaget calls it, “genesis”), while other solutions postulate that there is no process of development. By combining these two dimensions, six possible answers appear to the question of the nature and origin of knowledge (see Table 1).

As can be seen in this table, Piaget chooses the term “relativism” to define his epistemological perspective. On other occasions, and before he consolidated the term constructivism, Piaget also used the term “interactionism.” Both terms (relativism and interactionism) point to two of the fundamental characteristics of Piagetian constructivism: 1) knowledge is the result of the interaction between the subject and object (hence the term “interactionism”); and 2) in this process of interaction, the subject and object are both modified reciprocally (hence the term “relativism”). In fact, knowledge is always related to a subject’s capacity for assimilation (which changes throughout his/her development); at the same time, this changes the subject’s capacities, causing changes in how he/she understands the object. Piaget called this constructivist perspective “genetic epistemology.”

A clear example of construction, as conceived by genetic epistemology, is that related to the concept of the “object.” Piaget accepts that objects

are part of a reality that pre-exists any relationship that a child has with it. From the perspective of the child, however, the objects have to be constructed. This construction process is slow and extends throughout the first year and a half of life. In the early stages, objects are assimilated into action schemes (suck, grab, pull, etc.) and only exist as a function of these actions. Progressively, thanks to the coordination of these schemes, objects acquire a reality independently of the actions of the child. That is to say, they reach permanence. From this moment (at around 18 months), the child is able to understand that objects exist, even if he/she does not see or touch them. In this long process of construction, from the perspective of the child, objects change as their action schemes change. The final point is reached when permanence is achieved.

Defining constructivism in this way allowed Piaget to define himself in front of the two dominant positions in the epistemological debate: the nativist perspective and the empiricist perspective. In the former, the subject is given a clear role, but the difference with constructivism is that the nativist thesis purports that knowledge is already constituted from the beginning, at birth. There is no construction process. If we take the previous example of the object concept then, following the nativist thesis, the object already exists from the beginning and the baby knows that it constitutes an entity of its own from his/her first weeks of life. Against the latter empiricist thesis, Piagetian constructivism insists that, although objects exist independently of the subject, the subject’s knowledge of them is not extracted directly through their perception of them, but that the subject needs an active and transforming participation (Piaget 1980; Piatelli-Palmerini 1979).

Constructivism, Table 1 Different solutions proposed by Piaget concerning the nature and origin of knowledge (adapted from Piaget 1950)

	Non-developmental solutions	Developmental solutions
Object’s primacy	Realism	Empiricism
Subject’s primacy	Apriorism	Pragmatism
Indissociation	Phenomenology	Relativism

Piagetian Constructivism in Psychology

Piaget always maintained that epistemology had to rely on empirical data, so that it did not become mere speculation. In this way, according to Piaget, epistemology can be differentiated from philosophy (1972/1965). Piaget found that the main empirical support for his epistemology was in developmental psychology. He called this “genetic psychology.”

The numerous studies that Piaget and his collaborators carried out to study cognitive development constitute an essential contribution in their defense of the constructivist thesis. In these studies, which related to fundamental categories of knowledge such as space, number, quantity, logic, and symbol, children of different ages were interviewed about a problem scenario to discover their way of thinking, and how this way of thinking transformed with age.

To appreciate the characteristics of Piaget's theory of constructivism, we will attend to two basic questions: what type of knowledge is being built (i.e., what is constructed) and what are the mechanisms of this construction (i.e., how it is constructed).

What Knowledge Is Constructed

For Piaget, knowledge arises from the interaction between a subject and reality and, therefore, what indicates the subject's progress in knowledge is progress in the actions that the subjects are able to perform to solve a particular problem. Piaget distinguishes three well-differentiated periods (called “stages”) when analyzing how knowledge construction occurs.

In the first stage of development, the interaction between a baby and various objects is realized by sensory-motor actions, such as to suck, grab, and push, and these actions generate knowledge. In fact, when these actions are repeated in different situations, they maintain a framework, a structure, which Piaget defines as an “action scheme.” The emphasis of constructivism is not placed on the specific knowledge that children draw from their actions, as applied in isolation, but in the

consequences that the action schemes have when they coordinate with each other and constitute broader conceptual frameworks (known as “joint structures”) (Piaget 1971/1968).

For instance, an interesting process in the development of babies occurs when two schemes of action are coordinated, with one scheme becoming a means to achieve a goal. This happens, for example, when a baby moves a screen (first action scheme) to catch an object that is behind it (second action scheme). When this coordination of schemes progresses, there comes a moment, according to Piaget, in which they constitute structures that allow a new and deeper knowledge of reality. This is known as “normative knowledge,” a knowledge that is imposed in a necessary way to the subject. Another example of this kind of knowledge occurs when babies discover that, if an object moves from place A to place B, there is a movement from B to A that cancels the first movement. Or when babies discover that, even if an object has been hidden behind a screen, if they move the screen they will find it. These behaviors indicate that the concept of object has been constructed and it has been made possible, thanks to the coordination of action schemes. During this first stage (sensory-motor stage), the knowledge that is being constructed arises from a sensory and motor interaction of the baby with the environment. It is practical knowledge.

After a certain point (at the second year of age), a new constructive process begins. In this case, however, the child has to coordinate mental actions (called operations), rather than effective actions as in the preceding stage. Thanks to the function of symbols, the child can perform different actions mentally (instead of having to execute them practically). Some examples of these operations are to collect and separate objects, or to sort or classify them. The transition from action to operation means that the cognitive advances made by the child in the sensorimotor stage will have to be re-constructed, but now in the mental plane, in the plane of operations. This is a slow constructive progress that culminates toward 7 years of age, when children are able to coordinate mental operations with each other. By being

able to coordinate operations completely, the child's thought becomes more coherent, less egocentric, and reaches a greater degree of objectivity. Piaget calls this second stage the stage of concrete operations. A consequence of this achievement is constructing the concept of conservation: the knowledge that a dimension (e.g., mass, number, length, weight, volume) remains the same, although it may change its appearance. This knowledge, as occurred with the concept of object in the previous stage, has a normative nature. For example, in the case of the conservation of liquid quantity, the child deduces that there must necessarily be the same amount of liquid, if it has only changed its appearance and nothing has been added to or removed from the container.

Cognitive development does not end with this second stage, however. For Piaget, there is a final and definitive progress when a coordinated set of formal operations is constructed. These operations apply to the relations between hypothetical propositions, independently of their content. In this stage, the subject can deduce necessary consequences by reasoning in a hypothetical way, without paying attention to its content. His/her reasoning can be based on the formal relations between propositions (e.g., tautology, contradiction, necessary condition, sufficient condition). This is what Piaget calls the stage of formal operations. It culminates approximately at 15 years of age and consists, once again, of a cognitive reconstruction of what was achieved in the previous stage, but on a new level (that of hypothetical reasoning based on the logical relationships between propositions) (Piaget 1969/1966).

From the perspective of Piagetian constructivism, cognitive development can be described as a spiral, as a series of reconstructions on different levels: the level of actions, the level of concrete operations, and the level of formal operations. Each reconstruction consists of a stage of development that is qualitatively different from and integrates with the previous one. In each stage, new relationships – between actions, between concrete operations, and between formal operations – are possible. These new relationships allow for new ways of knowing the world. A

knowledge that is, increasingly, broader and more rigorous.

How Knowledge Is Constructed

According to Piagetian constructivism, there are clear discontinuities in the nature of the knowledge that appears alongside development. These discontinuities correspond to the different stages described above. From a functional standpoint, if we look at how the exchanges between subject and object are made, Piaget asserts that, throughout all development, interaction is guided by the same processes: “assimilation” and “accommodation.” Assimilation is defined as the incorporation of an object into preexisting cognitive structures. For example, incorporation means that an object takes on a meaning that it is interpreted. At the same time, however, there is a reciprocal process, called accommodation: the preexisting structures have to be modified according to the characteristics of each new object that is assimilated. Alongside development, therefore, there is a functional continuity to the extent that both processes always guide the exchanges between subject and object.

How can we explain that these processes are responsible for the progress that occurs from the sensory-motor stage to the stage of formal operations? Piaget proposes that the essential motor of this cognitive construction is a process of “equilibration” (Piaget 1969/1966). Equilibration is defined as the set of self-regulations that occur in the interaction between the subject and object (1985/1975). This granting of a fundamental role to equilibration does not mean that other factors, often proposed to explain the construction of knowledge, are unimportant. Piaget designates three factors: 1) organic growth and maturation, 2) experience related to actions (and operations) exercised on the physical world, and 3) social interactions and cultural transmissions. Piaget also argues that these three factors, although necessary, are not sufficient to explain the progress made in knowledge alongside development. The factor that drives these developments, the orchestra leader so to speak, is precisely this process of equilibration.

The self-regulations that occur in equilibration consist of actions that the subject performs in response to disequilibria that appear in his/her exchanges with the environment. The origin of these disequilibria can be diverse and of different complexity. They can appear before the impossibility that a baby faces in assimilating a new object to a current scheme of action, which requires them to regulate the action to avoid this disturbance. Disequilibria also appear in cases in which a problem has to be solved, as in the case of conservation tests in which the child must mentally compensate for the changes introduced by the experimenter in order to find the answer to the question posed. They also appear in many other cases in which the subject tries to solve a new problem.

These self-regulating processes – always in search of a more stable, more balanced exchange between subject and object – are responsible for building knowledge in a certain direction (such as obtaining knowledge that establishes a more stable equilibrium, that is more adapted to reality). In fact, within each stage of development, knowledge progresses in the direction of establishing more balanced exchanges between the subject and the environment. Conversely, these three stages can be viewed in succession as a progress toward forms of relationship with the environment that are increasingly broader and more flexible and, therefore, more stable and balanced.

The Creation of Novelties as New Possibilities

One of the central questions of any constructivist perspective is to account for the appearance of new knowledge, or “novelties”, so as to explain how novelties are produced throughout the construction process. Piaget’s answer is to defend that self-regulatory processes, which make new knowledge possible, correspond to the three stages of development described above. This knowledge, according to Piaget, is not previously pre-formed in the subject nor is it extracted from the objects directly. The activity of the subject is necessary to elaborate it.

One of the ways that Piaget proposes to address the issue of the production of novelties is to analyze, throughout the development process, how new possibilities are generated (Piaget 1987/1981) (see section ► [“Possible in Psychology”](#)). According to Piaget, updating any action or idea implies that, previously, this action or idea was considered to be possible. Hence, it is important to study how new possibilities are generated. At the same time, the generation of one possibility usually implies the generation of other possibilities.

According to Piaget, how the subject generates new possibilities varies according to age. Through a wide sample of studies, Piaget showed that, from the perspective of the child, generating new possibilities undergoes four stages. All the studies posed situations to children of different ages in which they had to imagine different possibilities (the different paths that a car can take between two places, how many different ways a square can be cut from cardboard, different ways to raise the water level of a container by introducing various objects, etc.). In the first stage, the child generates possibilities one after another, based on certain analogies between them. In the second stage, the child can anticipate several related possibilities (Piaget calls them “co-possibilities”) before updating them. In the third stage, the child manages to understand that the co-possibilities he/she updates are only some cases, among many other conceivable co-possibilities. Finally, in the fourth stage, the child realizes that the possibilities are unlimited. The results of these studies showed that the advances in a child’s generation of possibilities were closely related to the different stages of development.

Co-constructivism in Psychology

Piaget’s theory of constructivism is not the only constructivist perspective in psychology. Under his influence, throughout the 1980s and 1990s, the term “constructivist” was extended to other psychological theories. It was applied to any perspective postulating that knowledge is not

innate and does not come directly from the environment, but is made thanks to the activity of the subject. What then happens is that there are many ways to define what is meant by the subject's "activity." In psychology, this leads to very different theories, which can all be considered "constructivist" in a broad sense (Martí 1996). Among these, the theory that is based on the sociocultural psychology of Vygotsky and his followers (see section "Vygotsky") has been the most influential. This is called "co-constructivism" (Valsiner 1996).

The constructivism of Piaget, although it does not dismiss social factors as being necessary elements for the construction of knowledge, places emphasis on the interactions between the subject and the physical environment. From this perspective, the role played by other people is secondary. Co-constructivism assumes that the elaboration of knowledge cannot be explained by considering only the interactions between the subject and the physical world. It is also necessary to consider the fundamental role played by social interactions and culture in a construction (becoming, therefore, "co-construction," in the sense that it is a construction made jointly with other people).

The implications of this thesis, however, are different. The first is to contend that any interaction occurring between the subject and the environment (both social and physical) is located within a framework of pre-constructions, which have been generated throughout history, and which constitute a cultural legacy (Bronckhart 2012). These pre-constructions consist of the collective activities and accumulated knowledge that govern the exchanges between people of a specific social group. All knowledge construction, therefore, has its origin in these cultural pre-constructions.

The second implication is to argue that an important part of cultural legacy is semiotic in nature. Therefore, the construction of knowledge is a semiotically mediated activity and, in this mediation, language acquires a fundamental importance. Vygotsky attached great importance to the fact that, when psychological processes are semiotically mediated, they are profoundly

transformed. In addition, he argued that signs (e.g., language, which is a particular and very powerful case in the system of signs) have a social origin.

The third implication is the idea that interpersonal relationships are constitutive elements of any knowledge construction, to the extent that knowledge is constructed under the guidance of other people. Vygotsky introduced the concept of the "zone of proximal development" (see section ► ["Zone of Proximal Development"](#)) to demonstrate the importance of the support and help of other people in any development process. Hence, for co-construction to occur, development and education are two interdependent processes.

Conclusion

Constructivism constitutes an epistemological position that differs from nativism and empiricism. From this position, it can be asserted that knowledge is the result of a slow process of construction and that the subject has a clear role in this construction. These are the general features of any theory called "constructivist." These general postulates can also give rise to different psychological, biological, mathematical, or educational theories.

Piaget was one of the authors who defended this epistemological perspective most clearly. He proposed a set of postulates based on empirical data to show how subjects build their knowledge throughout their development. His theory of developmental psychology was founded in epistemological arguments. He defended the importance of the interactions between the subject and objects from which different knowledge emerged throughout the subject's development. He proposed that the construction of this knowledge could be described in terms of stages; each stage corresponded to certain cognitive achievements of different complexity. Finally, he explained that knowledge can be constructed thanks to self-regulating mechanisms. Considering that one of the central problems of any constructivist perspective is to explain the appearance of novelties (new knowledge) and that novelties, before being

updated, have to be possibilities, Piaget proposed a series of studies on how possibilities are generated alongside development.

The way in which Piaget specifies how knowledge is constructed is not the only psychological solution to this question. An interesting alternative is the one that defends the sociocultural theory of Vygotsky. Although in his writings Vygotsky did not explicitly use the term “constructivist” to describe his theory, his proposal stands out from nativism and empiricism. Unlike Piaget, however, Vygotsky grants a crucial role to social interactions and culture in the construction of knowledge.

Counterfactual Thinking

Felipe De Brigard

Duke University, Durham, NC, USA

Keywords

Counterfactual thinking · Contrary-to-fact · Counterfactual potency · Functional theory · Upward-downward counterfactual thoughts

Definition

The term “counterfactual” was coined by philosopher Nelson Goodman (1947) to capture Roderick Chisholm’s more convoluted locution “contrary-to-fact” (Chisholm 1946). “Counterfactual” was initially used in reference to conditional statements with false antecedents such as “If kangaroos had no tails, they would topple over” (Lewis 1973). Since, in reality, Kangaroos do have tails, this counterfactual conditional expresses a relation between a false antecedent and its consequent. The concept behind the term, however, has a longer history. For instance, Newton, Leibniz, and Laplace famously discussed various philosophical issues involving ways in which the world could have been, and many argue that Hume employed counterfactual considerations to define *cause*. Nevertheless, for most of the twentieth century, research on the meaning of counterfactual statements was very much confined to philosophy, and to areas such as logic, semantics, metaphysics, and epistemology. There was very little, if any, psychological research on the nature of the thoughts expressed by counterfactual statements.

In October 1982, in his wonderful yet short-lived Scientific American column *Metamagical Themes*, cognitive scientist Douglas Hofstadter playfully conjectured that the crux of creativity was to be found in the fact that our minds tend to slip, nondeliberately yet nonaccidentally, into “variations of a theme” of which counterfactual thoughts, or “subjunctive hypothetical replays,” are of the essence. Three years later, he appended

a postscriptum to said column in which he referred to Kahneman and Tversky's (1982) seminal work on the simulation heuristic as spearheading research in the psychology of counterfactual thought. The following three decades saw an explosion of research in the psychology of counterfactual thinking, initially confined to the fields of social psychology and behavioral economics, but later on expanded so as to include developmental and cognitive psychology and, more recently, neuroscience. By necessity, then, this short entry is very selective, and structured around four specific questions: (1) When do people engage in counterfactual thinking? (2) Why do we generate counterfactual thoughts? (3) What do people think when they engage in counterfactual thinking? (4) How do we generate counterfactual thoughts?

When Do People Engage in Counterfactual Thinking?

Kahneman and Tversky's (1982) work on the simulation heuristic spearheaded experimental research on the psychology of counterfactual thinking. In this work, Kahneman and Tversky surveyed a handful of results from vignette-based studies and suggest that people tend to counterfactually mutate events that antecede a certain outcome according to three "directions": *Uphill* changes introduce nonactual unlikely events, *downhill* changes delete actual surprising or unexpected events, and *horizontal* changes simply swap two variables that are perceived as neither more nor less likely. They chose to use these terms metaphorically, as they convey the sense that the same distance traveled uphill takes much more effort than when it is horizontal, and this in turn takes more effort than when it is downhill, which helps to explain the second observation of their influential paper: that people are much more likely to engage in downhill relative to both uphill or horizontal counterfactual thoughts. Thus, according to Kahneman and Tversky (1982: 208), the simulation heuristic, which they claim we employ for counterfactual thinking, is biased in favor of downhill changes. But why?

A preliminary answer as to that question had to wait four more years, until the publication of Kahneman and Miller's (1986) influential "norm theory." On this account, abnormal events or experiences increase the salience of counterfactuals that are congruent with the normal state of affairs. Consider a bicyclist who takes an abnormal route home from work and is hit by a car. Intuitively, when reflecting back on the event, the biker may likely think "If only I had taken my normal route home, I wouldn't have been hit." By contrast, if the biker had taken their usual route, it is less likely that they would have thought, counterfactually, "If only I had taken a different route, I wouldn't have been hit." Thus, when extraordinary or abnormal events occur, we are more likely to mentally mutate them toward the norm, much more so than we are likely to mentally mutate ordinary or normal events away from the norm.

This "exceptionality effect" in counterfactual thinking was shortly followed by the discovery of other "fault lines" in our imagination (Hofstadter 1985). For instance, people tend to counterfactually think more about controllable relative to uncontrollable events (Giroto et al. 1991). Consider these two situations. In one, a person – call them Oan – leaves a bit earlier from their office and, on the way home, decides to stop at a bar to get a drink. Unbeknown to him, his spouse is having a heart attack. Had Oan arrived on time, he would have been able to save her. The second situation is just the same, except that Oan left early but was caught in traffic. In neither case, Oan was able to make it on time to save his spouse, but when confronting these two situations, people overwhelmingly think that Oan would be much more likely to engage in counterfactual thinking and imagine "what if I hadn't stopped at the bar," relative to the situation in which the reason for his delay was not under his control. This "controllability effect" is also related to an "action effect," famously described by Kahneman and Tversky (1982). Suppose Ema holds shares in company A, but decides to switch to company B. As a result, she loses \$1,000. By contrast, Ava holds shares in company B, and considers changing to company A but decides

against. She also loses \$1,000. Despite the fact that both lost money, people overwhelmingly think that Ema – who acted – would feel much worse than Ava – who did not – and would be much more likely to counterfactually think “If only I hadn’t change companies, I wouldn’t have lost \$1,000.”

Another well-documented effect is “temporal order.” Imagine a coin-toss game in which two people win \$1,000 if they both toss a coin and both land in the same face. Person A goes first, and she tosses heads. Person B goes next, and she tosses tails. When asked how things would have been better for them, most people counterfactually imagine the alternative in which person B tosses heads, rather than person A tossing tails, even though both alternatives would have yield a win (Miller and Gunasegaram 1990). The tendency to modify the most recent event also occurs with longer sequences (Segura et al. 2002), and even when the events are historical and take place over much longer time periods (Tetlock and Belkin 1996).

When first proposed, norm theory suggested that effects such as temporal order and exceptionality in counterfactual thinking biased judgment and decision-making. As such, these biases or tendencies were seen as an impediment to sound judgment. However, as more and more of these “biases” started to emerge, not only it became suspicious that they all reflected irrational judgments, but also they became harder to account in terms of norms alone. To offer an alternative explanation, Petrocelli et al. (2011) put forth a theory known as *counterfactual potency*. According to their view, the degree and strength of influence a counterfactual thought would exert – what they term “counterfactual potency” or CP – is proportional to the multiplicative product of the perceived likelihood of the antecedent of the counterfactual – which they term “if likelihood” or IL – and the perceived conditional likelihood of the alternative outcome, given the antecedent – the “then likelihood” or TL. Briefly, then, $CP = IL \times TL$. As such, when a person judges the likelihood of an antecedent to be very high, and the likelihood of the consequent conditional on the antecedent to be high as well, then

the counterfactual would be more likely to be entertained than when either IL or TL are very low. To what extent the theory can manage to explain all known – and yet-to-be found – effects on counterfactual thinking remains to be seen, as it is not always terribly obvious how exactly to quantify both if and then likelihoods in all situations.

Why Do We Generate Counterfactual Thoughts?

To better understand why people engage in counterfactual thinking, Roeser and Olson (1995) offered the first formulation of their *functional theory of counterfactual thinking*. According to them, counterfactual thinking serves two psychological functions, and each function is related to a specific structure of a counterfactual thought. Upward counterfactual thoughts, which consist in imagining how a past event could have been better, are associated with a preparative function. More precisely, the theory suggests that we engage in upward counterfactual thinking when we fail to obtain a positive outcome or desired goal, and thus imagining achieving the failed outcome or goal may help to improve our chances of doing so in relevantly similar future situations. Thus, the soccer player that failed the penalty kick, by aiming a bit too far to the right, may imagine what would have happened had she aimed leftward so that the next time she faces another penalty kick, her chances of making the goal would improve. Moreover, upward counterfactuals typically elicit regret, an emotion that is thought to help motivate improvements in future behavior.

By contrast, downward counterfactual thoughts, which consist in imagining how a past event could have been worse, were thought to serve an affective function. Specifically, by mentally simulating a worse outcome than what it actually occurred, people may feel better about what actually happened. A person who survives a car accident, for example, may imagine how it could have been much worse – e.g., they may imagine having been seriously injured – in order

to feel better about the fact that their car is now totaled. As a result, downward counterfactual thoughts are typically associated with feelings of relief. Indeed, the affective consequences of both upward (i.e., regret) and downward (i.e., relief) counterfactual thoughts were interpreted according to the emotional amplification hypothesis (Kahneman and Miller 1986), which was proposed as part of the norm theory. According to this hypothesis, upward counterfactual thoughts tend to heighten negative emotions, whereas downward counterfactual thoughts tend instead to heighten positive ones.

One of the most serious challenges to the functional theory of counterfactual thinking came from Markman and McMullen (2003, 2005) in their Reflection and Evaluation Model (REM). According to the REM, when people engage in counterfactual thinking, they may do so via two different modes of mental simulation. One the one hand, when mentally simulating an alternative possibility, a person may focus on the content of the simulated event, and thus their affect would be biased toward the feeling that would have been elicited had the imagined event been real. This process of *assimilation* leads people to think that the imagined content is part of their current self and thus to simply *reflect* about it, without contrasting it with reality. The soccer player that failed the penalty kick and engaged in upward counterfactual thinking may decide to just focus on the simulated content (i.e., the imagined goal), without regard to what actually occurred (i.e., the missed goal), and simply relish on the possibility of having scored. This mental experience, rather than eliciting regret, may elicit joy instead. Conversely, when the car accident survivor simply focuses on the simulated content, they may feel sick to their stomach by the sheer contemplation of being seriously injured, without regard to the fact that they actually are not.

The reflective mode of engaging in counterfactual thinking contrasts with the *evaluative* mode, which stems from a *contrastive* process, in which a person focuses not on the simulated content but on the contrast between the imagined situation and the situation they are in when imagining. By *excluding* (as opposed to assimilating) themselves

from the imagined counterfactual situation, people shift their affect away from the feeling they would have felt had the simulated content occurred, eliciting the opposite valence. For example, when the soccer player evaluates the unobtained outcome (i.e., a goal) against the current state (i.e., having missed), regret ensues, just as relief is felt by the driver who contrasts the possible outcome (i.e., being injured) against the actual, more desirable outcome (i.e., having survived the crash without injury). Thus, according to the REM, the emotional amplification hypothesis only explores some affective consequences of imagining alternative ways in which past events could have occurred, as these can vary depending on the psychological mode one adopts when engaging in counterfactual thinking.

Given the findings and observations from the REM, the affective and motivational consequences of counterfactual thinking were revised in an updated version of the functional theory (Epstude and Roese 2008; Roese and Epstude 2017). Now, according to the revised version, counterfactual thinking serves mainly a preparative function whose object is to improve or modify future behavior, while the affective consequences of such simulations are seen as merely secondary. However, the updated functional theory suggests two “pathways” through which counterfactual thinking contributes to behavior modification. The first is a content-specific pathway, through which the information represented in the counterfactual thought directly transfers to a possible future situation. For instance, the soccer player that imagines having scored, by kicking the ball slightly leftward, may later on recall that very content and correct her movements accordingly. By contrast, the second pathway is content-neutral, whereby counterfactual thinking impacts future behavior independently of the content represented in the mental simulation but rather via emotion, affect, or motivation.

More recently, it has been suggested that in addition to a forward-looking function, counterfactual thinking may also serve a mnemonic role. Based upon findings from memory research suggesting that when autobiographical memories are reactivated, they become labile and prone to

modification, engaging in counterfactual thinking may help to modify some of the mnemonic contents of reactivated memories (De Brigard et al. 2019). In a recent study, for instance, Parikh et al. (2021) showed that when anxious individuals reactivate negative autobiographical memories and imagine worse ways in which the remembered events could have occurred instead, their feelings of regret later on are reduced relative to simply remembering the event without generating a downward counterfactual. However, the precise nature of this alleged mnemonic role for counterfactual thinking is still an open question.

What Do People Think When They Engage in Counterfactual Thinking?

In addition to understanding the circumstances in which people tend to engage in counterfactual thinking, as well as their functional roles in our mental life, researchers have also tried to answer the tricky question of what exactly comes to mind when we think counterfactually. One of the most influential approaches to answering this question was initially proposed by Byrne (1997) building upon the conceptual machinery of *mental models* (Johnson-Laird 1986). According to her view, when people think counterfactually, they entertain two mental representations: one with the imagined alternative and one with the actual, known fact. Thus, when someone thinks “If kangaroos had no tails, they would topple over,” they are prompted to represent the conjunctive fact “Kangaroos have tails and they don’t topple over” as well as the conjunctive counterfactual possibility “Kangaroos have no tails and they topple over.” Typically, people entertain as few possibilities as needed to make sense of a counterfactual. Thus, initially, people likely do not represent the conjunctive possibility “Kangaroos have tails and they topple over” or one in which kangaroos have no tails and manage to not topple over, perhaps by some other means. Of course, given more time, people may be able to represent all sorts of counterfactual possibilities. But the intuitiveness of the initial dual-possibilities, the fact that these two juxtaposing representations are the

ones that first come to mind, suggests – according to Byrne – that such is the nature of the mental model with which we immediately interpret a counterfactual statement (Byrne 2002, 2016).

A more recent proposal, put forth by Phillips and colleagues (e.g., Phillips and Cushman 2017; Phillips et al. 2019), seeks to answer the same question but from a different perspective. Specifically, their interest is to understand how people select a subset of possibilities, among all of the perhaps infinitely many possibilities that there are, when considering counterfactual alternatives to reality. To use a variation on a theme from Hofstadter (1985), consider the situation in which you walk into a pizza parlor and you are handed a slice of pizza. As you get it closer to your mouth it slips off your hand and lands on the floor. Think about the barrage of possibilities that could have come to mind when thinking about what might have prevented the pizza slice from falling so that you could still enjoy it. Most likely you may think “if only I have grabbed better” or “if only my reflexes were faster so I could have caught it mid-air.” But there are lots of other possibilities you could have considered: “if only gravity had stopped for a second,” “if only it had happen to the person behind me in line rather than me,” or “if only it was socially acceptable to eat things off the ground.” All of those are possibilities that, had they been actualized, would have allowed you to still eat your pizza slice. Nevertheless, most likely they would not have come to mind. But why?

Phillips suggestion is that when we sample possibilities, our default representation is constrained by what we find both likely and valuable. When applied to counterfactual possibilities, their proposal implies that our initial or default considered possibilities are the result of a three-step process. First, there is an initial partitioning of possibilities that is likely task-dependent. The next step consists in an adaptive sampling that depends on two factors: the probability of the possibility and its adaptive value. This adaptive sampling process, which is not task-dependent but rather uniform across tasks, leaves a smaller subset of possibilities to be further considered and evaluated. Thus, in a third and final step, people

reason and decide among this much smaller set of possibilities (Phillips et al. 2019). In a beautiful demonstration of the power of their model, Phillips and Cushman (2017) presented participants with a situation in which a student, Mary, forgot her homework. Then they were presented with a number of different possibilities, with different modal terms, as to what she might do, and they were asked to judge whether or not it applies. For instance, they may have read “Mary could forge an excuse note,” “Mary ought to forge an excuse note,” “Mary might forge an excuse note,” etc. Critically, some of the participants had to answer very quickly, while others had more time. They found that, when participants had more time, their responses varied widely. By contrast, when they were under time constraints, their pattern of responses was very uniform, and highly constricted by morality. More precisely, when considering the possibilities available to Mary, most people’s default intuition is constrained by what Mary ought to do, suggesting that the sampling of possibilities is initially constrained by moral value.

Phillips’ model is a phenomenal development toward our understanding of the computational underpinnings of counterfactual and hypothetical reasoning in general. Nevertheless, it still leaves a number of intriguing questions unanswered. What determines, for instance, the initial partitioning of possibilities? While they may be task-dependent, it is worth wondering what features of the task influence the initial partition of possibilities, or whether there is some other factor, prior to the task itself, that may influence how we initially partition the set of possibilities we subsequently sample. The answer, intriguingly, may come from a different area of research: memory.

How Do We Generate Counterfactual Thoughts?

One of the most remarkable findings in the cognitive neuroscience of memory, in the last few decades, is that our capacity to imagine possible personal future events is supported by some of the same neural structures required to remember our

personal past – a set of brain regions commonly referred to as the “brain’s default network.” To account for this commonality, Schacter and Addis (2007) postulated the *constructive episodic simulation hypothesis* according to which both episodic memory and episodic future thinking involve the recombination of past episodic details into mental simulations depicting either actual past or possible future events. As such, the common engagement of these mutual operations explains the fact that both require similar neural substrates. Interestingly, soon after it was found that some of these core neural structures have been also implicated in our capacity to imagine alternative ways to past personal events that could have occurred but did not – a variety of counterfactual thoughts that have been dubbed *episodic counterfactual thinking* (De Brigard et al. 2013; Schacter et al. 2015). As such, De Brigard et al. (2013) extended the constructive episodic simulation hypothesis to cover not only episodic future but also episodic counterfactual thoughts.

Further studies showed that other varieties of counterfactual thoughts did not rely on the same core regions involved in episodic memory and future thinking. For instance, counterfactual thoughts that involved objects, as opposed to people, were less likely to engage core regions of the brain’s default network (De Brigard et al. 2015). In another study, Parikh et al. (2018) asked participants to think counterfactually about past personal episodic memories or to think counterfactually about semantic facts (i.e., “imagine that Iowa City was the capital of the US”) while undergoing fMRI. Their findings show that while episodic counterfactual thoughts clearly recruited core regions of the brain’s default network, semantic counterfactual thoughts engaged regions outside of it, primarily associated with semantic memory and linguistic processing. More recently, Khoudary and colleagues (2022) conducted a neuroimaging study contrasting internal episodic counterfactual thoughts – in which the participant imagines that something they could have done would have brought a better outcome to a past personal negative event – against external episodic counterfactual thoughts, in which participants thought of alternative ways in which a change in

circumstances that was not up to them would have brought about a better outcome to a past negative event. They found that, while both kinds of counterfactual thoughts tended to recruit regions of the brain's default network, some were differentially recruited as a function of whether the locus of action in the counterfactual thought was internal to the self or external to the circumstances surrounding the event.

Taken together, the results of these recent findings in the cognitive neuroscience of counterfactual thinking strongly suggest that not all counterfactual thoughts are created equal, and that depending on whether the counterfactual alternatives depend on episodic or semantic memory, people may likely engage different cognitive processes (De Brigard and Parikh 2019). Indeed, these findings dovetail with an intriguing study by Giroto et al. (2007) in which they document an actor-reader asymmetry in counterfactual thinking. Recall, from Section “[Why Do We Generate Counterfactual Thoughts?](#)”, the “controllability effect.” It says that, when presented with vignettes involving alternative possibilities to an action or decision, people are more likely mutate about what was under the protagonist control rather than uncontrollable aspects of the situation. However, what Giroto et al. (2007) show is that when the protagonist is not someone in a vignette but rather themselves, they do not mutate aspects of what they could have done but rather aspects of the situation that were not up to them. These findings suggest that, even when facing exactly the same choice, what we think counterfactually about others may not be the same as to what we think counterfactually about ourselves.

Summary

The science of counterfactual thinking is going through a very exciting moment, and findings keep piling up. As such, this brief entry only touched the surface of what is now a very large area of research. Findings from ethology and comparative psychology, for instance, are starting to shed light on which nonhuman animals can engage in counterfactual thinking and under

what conditions. Likewise, there is a large amount of research on the development of counterfactual thinking, the results of which are casting light on the question of when that ability emerges in children and how it develops through infancy and adolescence. Although fewer, there is also research on how counterfactual thinking changes in both pathological and nonpathological aging, as well as the impact of different brain illnesses on our capacity to think about alternative ways past events could have occurred. Finally, there is also an enormous amount of fascinating research connecting counterfactual thinking to other cognitive processes, such as moral cognition, decision-making, and causal reasoning, among others (for a recent review, see Byrne 2016).

Crealectic Intelligence

Luis de Miranda
Uppsala University, Uppsala, Sweden

Abstract

The emerging crealectic frame posits that there are three complementary and effectual domains of intelligence, namely analytic, dialectic, and crealectic, being alternatively or complementarily used in human interactions with the world. The focus of crealectic intelligence is the relative possibilization and local realization of absolute possibility, the becoming real, biological, and social of creation. This multimodal externalization and asymptotic unification of a cosmological flux expresses itself via three realms of possibilization: physical (corresponding to

analytic intelligence), psychological (corresponding to dialectic intelligence), and philosophical (corresponding to crealectic intelligence). But the philosophical possible is not merely abstract; it originates a generative process of exteriorizations, interiorizations, dissolutions, and unifications transforming the possible into realities. The term “crealectics,” coined by philosopher and author Luis de Miranda (*Paridaiza*. Plon, Paris, 2008), is a compound of “Creal” (from “creative” and “Real”) and of two possible suffixes: “logos” (from the Greek word designating a universalized meaning) or “ektos” (from the Greek root meaning “toward the outside,” “outer,” or “external”). The ontological core of crealectics, the Creal, is the immanent process of creation understood as a ubiquitous stream of absolute possibility exteriorizing itself. For a crealectician, philosophy is not the mere logical analysis of truth conditions, but the self-questioning enterprise of thought regarding its own possibilizing and world-making power.

Introduction: Multifarious Intelligence

The crealectic frame posits that there are at least three complementary modes of intelligence, namely *analytic* (an objectifying discretization of the real in which machines may excel), *dialectic* (which deals with meaningful and often bipolar contrasts between entities or positions), and *crealectic* (which deals with potentials, actualizations, and unifications of absolute multiplicity). No healthy society may be possible without a holistic harmonization of these three performative aspects of thinking.

While the idea that there are several kinds of human intelligence (see ► “[Intelligence](#)”) became mainstream by the end of the twentieth century (Sternberg and Kaufman 2011), there is no general agreement on what these different kinds might be. The very etymology of the word

intelligence is ambivalent, between the two roots *inter-legere* and *inter-ligare*. Intelligence can be about *inter-legere*, to read between the lines, to distinguish, and to discriminate – “the world is an immense chaos of interactions, but in this immense chaos of interactions comes a human being who will know how to choose from this multiplicity” (Jousse 2016, p. 29). Yet, the root of intelligence can also be *inter-ligare*, to create links and connections: “Discoveries consist of bringing together ideas [...] that are susceptible to join but that had not been hitherto been joined” (ibid.). Whether intelligence consists in picking and distinguishing parts by a process of division and segmentation, for instance, via the analytic method in science; or in discovering wholes, syntheses, and unities by a process of association, for example, in dialectic thinking; or, third, and more actively, in generating actualizations of hidden potentialities (see ► “[Potential](#)”) – not to speak of the various historical, cultural, and disciplinary variations in defining intelligence around the globe – its polysemy of practices confirms the necessity of abandoning the view that intelligence is a universal form of manipulating symbols, one that could eventually be fully systematized in a series of protocols or algorithms. The Crealectic approach is particularly interested in the aspect of intelligence that deals with the philosophical possible and its actualizations.

The slow but steady development of the domain of “artificial intelligence” (AI) since the coining of the term in 1956 by John McCarthy et al. (O’Regan 2012) has not only added a new layer of complication to the understanding of what minds can do (Jacob 1997), but it has also in contradistinction induced the question of what “natural intelligence” might be (de Callatay 1992; Estep 2006). By natural here, we mean what a living human intelligence can access without the help of computers, leaving open for further debate the question of animal, plant, or alien intelligences. In order to define natural intelligence, one needs to provide a definition of what nature is, at least axiomatically. This is what the notion of “crealectic intelligence” does, by equating the essence of Nature with the process-philosophical concepts of “Creal,” “Creative Real” (de Miranda

2017, 2020a), “foundational process of creativity” (Whitehead 1929, p. 160), or “creative evolution” (Bergson 1911).

Definition and History

Crealectic intelligence is natural intelligence inasmuch as the essence of Nature – and therefore of Culture – is defined as a creative process of externalizations, interiorizations, dissolutions, and unifications grounded in absolute possibility. The term “crealectics,” originally coined by philosopher and author Luis de Miranda (2017), is a compound of “Creal” (from “creative” and “Real”) and of two possible suffixes: “logos” (from the Greek word designating a unifying meaning) and “ektos” (from the Greek root meaning “toward the outside,” “outer,” or “external”). The word Creal (French *Créel*) itself was coined by de Miranda in his French science-fiction novel *Paridaiza* (2008, English translation 2020), in which the characters are immersed in a totalitarian duplication of the Earth created through virtual reality and AI technologies (see ► “[Virtual Reality](#)”), an addictive simulation (see ► “[Virtual Reality](#)”) that maintains humanity in a state of sensual dependence and immaturity.

A group of rebels manages, however, to create a liberating virus that shall free the alienated users of Paridaiza, via a coded signifier which they initially call *Strait*. Magellan^x, the first insurgent avatar who benefits from the Strait treatment, has the vision of “a world he has spontaneously named the Creal.” (2020, p. 151). As per the published English translation of the novel (2020b):

“You’re going to think I’m on drugs. The first impression I had was of being in a different universe from Paridaiza, maybe even an opposite one. There was a kind of explosion, and I found myself in the corner of a sort of cloister, with a garden and a fountain.”

“Did it look like a place you’d seen before?” asks Clara^x.

“Nothing was familiar, not even the smells, but at the same time I felt at home. I felt like I was inside a living kaleidoscope that would obey my commands. And it was as if there was honey flowing

in my veins, an intense flow of desire. The path leading to the fountain formed a kind of maze that shifted and changed with every step I took. Shining, brightly-colored shapes were transforming constantly. I looked up and realized that the cloister didn’t have any walls, only peristyle columns. How can I describe it? I felt like this world was my own creation in a way, but at the same time I was only the instrument of a divine harmony.” [...]

“But why Creal? Why did that neologism come to you so suddenly out of nowhere?”

“I don’t know. I felt like I was entering the very depths of imagination and the heart of reality at the same time.”

“And you felt good?”

He concentrates, searching for the right words.

“Yes, it was truly a feeling of joy and confidence. I felt powerful, too, but with a gentle, harmonious kind of power.”

“Was that the effect of a series of coincidences? Of synchronicity?”

“It was like I’d touched the very essence of my own being. I felt like everything was connected.”

Gagarina^x’s face lights up.

“This magical cloister with a fountain in the center... that exactly matches the description of what people called Paridaiza in the time of the prophet Zoroaster. The true Paridaiza, the one represented on my Persian rug, and not a gilded prison filled with greedy avatars. That is your Creal: the secret of the original Paridaiza.”

“What secret?”

“None other than our spiritual roots. The yearning creativity that is the very essence of life. The imaginative desire that triumphs over our sinking, our collapse. The ancients called it the Poem of the Cosmos.”

“You seem to know a lot about it. What does any of this have to do with the code word *Strait*?”

“The Creal is the strait.” (pp. 151–154)

From the context of the fictional birth of the signifier, the reader may observe that Creal is defined as the “yearning creativity that is the very essence of life” and that, as a human essential possibility, it points to a harmonious unification of the subjective and objective experiences of the world.

The idea that creation or creativity is an immanent rather than only transcendent cosmological principle is typical of process philosophies, both

Western and Eastern, for example, in Heraclitus (Holm-Hadulla 2013, p. 297), Taoism (Yu 1981), Bergson, or Alfred North Whitehead for whom “Creativity is the universal of universals characterizing ultimate matter of fact.” (1929, p. 31). This onto-generative notion of creative becoming (Cheng 2018) has also been equated with a becoming-world of sublimity or absolute possibility (de Miranda 2020a). The object of crealectic intelligence is thus the relative possibilization and realization of possibility, the constant becoming real, biological, and social of natural creation, and the multimodal externalization and adunation of the multiple as source. While the generative concept of Creal is an all-encompassing ontological *a priori*, crealectic intelligence is an art or process of actualization more or less present in any singular transformation of the world. The more a protocol is repeated automatically, the more its crealectic capacity to actualize the possible is reduced. This is why a world ruled by computers, algorithmic standards, pervasive norms, bureaucracy, and other forms of “anthrobotics” is a danger to our relationship with absolute possibility (de Miranda, Ramamoorthy and Rovatsos 2016).

Crealectic Intelligence Versus Analytic Intelligence and Dialectic Intelligence

The experience of awe (see ► “Awe”), wonder (see ► “Wonder”), admiration, or imaginative questioning, which Aristotle and Descartes considered to be attuned to the origin of philosophy, may be seen as superfluous in sociotechnical protocols which are attached to an analytic exhaustion or exploitation of the Real. Mundane practices of engineering or mathematical ordering tend to keep the imaginative or desiring subject out of their equations in order to achieve an operational description and management of a system or problem. The early inventors of computational thinking were already aware that an essential part of intelligence was left behind in their analytic endeavors, namely a relationship to creativity and truth. When Charles Babbage and Ada Lovelace designed the first “Analytical Engine” by associating analysis with a mechanical function

of “operation” (Menabrea 1961, p. 247), Lovelace was careful to add: “The Analytical Engine has no pretensions whatever to originate anything. It can do whatever we know how to order it to perform. It can follow analysis; but it has no power of anticipating [...] (see anticipation) [...] relations or truths.” (p. 284). Analytics cannot by itself provide meaning, nor creative unification.

Analytic forms of intelligence were, however, a significant step in human evolution. Some 18 centuries ago, in his account of Aristotle’s *Analytics*, Alexander of Aphrodisias wrote that the one who “uses analysis [...] reduces composite bodies into simple bodies” (c.200 CE, 49, §2.4), thus separating an unknown into parts that are known (Arnauld and Nicole 1996, p. 200). Analytic elements manifest as what Noam Chomsky called a “surface structure” (1968, p. 30), represented by discrete symbols such as letters, code, labels, or forms; analytic intelligence thus considers reality as a readable corpus or text. It is a moment of distinctive literacy facilitating communication and the effectual manipulation of the Real. The analytic moment is the consideration of the world as possible syntax instead of chaos, or, in the language of artificial intelligence, patterns versus noise.

Searle’s famous distinction between syntax and semantics (1980) aimed at explaining why computers do not have an understanding of what they do and therefore cannot be said to be intelligent: “Computation is defined purely formally or syntactically, whereas minds have actual mental or semantic contents, and we cannot get from the syntactical to the semantic just by having the syntactical operations and nothing else” (Searle 2010, p. 17). Beyond these traditional objections to artificial intelligence, there is what we might call the Whiteheadian objection to the belief that analysis and its concreteness are sufficient to understand the Real: analytic intelligence, while useful for purposes of manipulation and operability, often ends up mistaking the abstract object for the concrete in a “fallacy of misplaced concreteness” (Whitehead 1926, p. 64). Out of habit or cognitive bias, we tend to believe that the parts, units, or functions that we distinguish and name are truly there in the real world, like cogs in a machine rather than metaphors. If

we take the example of mental health diagnoses, such as bipolarity, depression, or attention deficit hyperactivity disorder, the fallacy of misplaced concreteness pushes individuals to consider these diagnoses as describing their essential identity or inner nature. Seeing their soul as a psychiatric object rather than a site of self-possibility, these individuals are led to believe that other objects such as pills, via the mechanical law of causality, can regulate their being in the world.

Yet, phenomena of reality ambivalence (see ► [“Tolerance of Ambiguity”](#)) happen precisely because our cognition is not only analytic but also cocreative (Berthoz 2012). Our consciousness produces semblances of emergence (see ► [“Emergence”](#)) and meaning that supersede the sum of the observed parts and cannot be explained by strict analysis (Murphy and Stoeger 2007). In the past, analytic philosophers, tempted by materialism and the ideology of concreteness, have ironically called this surplus of meaning the “ghost in the machine” (Ryle 2009 [1949], p. 5). According to the crealectic frame, to call what we experience but cannot fully analyze, measure, demonstrate, or materially evidence a “ghost,” or speculative superstition, partakes in a reductionism that can be “detrimental both to good science and good human living” (Thompson 1997, p. 219). Ultimately, it is claimed that crealectic intelligence is already present in protocols that are usually seen as purely analytic, for example, the selection or distinction between useful data and neglectable noise.

Social intelligence implies a discursive negotiation and a creative focus that requires the concurrent display of dialectics (see ► [“Dialectics”](#)) and crealectics. Since Plato, dialectic intelligence designates an interpretative conversation in which there is a more or less rational tension between different or agonistic perspectives (from *dialegesthai*: to talk through). Dialectics is “the progression of thought through the appearance of oppositions within one and the same unity” (Bloch 1983, p. 288). This form of thinking can be performed between different subjects or within the same personal mind, as in Socrates’s inner dialogue with his guardian divinity, his daimonion (McMahon 2013, p. 40), or as in Descartes’

cogito, which can be defined as the human capacity for internalized individual dialectics, a form of consciousness that is capable of self-contradiction or self-examination.

In Hegel’s variant, dialectic intelligence describes the ubiquitous and necessary unfolding of a time-dependent process of negations and performative contradictions toward the realization of absolute Spirit. Hegelians believe that the Real is itself dialectical, and therefore that dialectic intelligence is a privileged form of deterministic realism leading to objective knowledge: “the dialectical constitutes the moving soul of scientific progression” (Hegel 1817, §81). In Hegelian dialectic consciousness, a proposition and its opposite can be both true, thus apparently ignoring the law of noncontradiction common in analytic logic. For instance, daydreaming and working: Every artisan or creator knows that daydreaming is not the opposite of working, but a modality of making-possible. Individual, bilateral, or collective forms of dialectic intelligence rely on polarities, tensions, and potential contradictions in a process that is ideally moving toward a form of reconciliation, resolution, or synthesis that reflects the movement of the “World-Soul” toward the realization of freedom on earth (Hegel 1806, p. 114).

The crealectic view argues, however, that when fetishized as a one-size-fits-all tool, as for example in the Marxist variant, or the Sophists’ version of the Ancient Greek variant, dialectics sometimes forces unnatural syntheses. In the agonistic world of dialectics, the illusion might be that there is not enough space for all, and it becomes difficult to identify if a synthesis is logical or rather belongs to a power struggle between different interests. Few can avoid being emotional in an antagonistic dialogue, and even Hegel admitted the importance of passion in dialectic unfolding. Hypercommunitarian times demonstrate the pitfalls of dialectics: Any legitimate position of dominance can be seen as a scandalous usurpation. Incessant phenomena of polarization of worldviews, accelerated by digital echo chambers, manifest a possible enclosure of dialectics into a friend-enemy or same-different combat.

The dialectic stage of understanding is necessary to transform a reading of signs into a

deliberative interpretation that subsumes real or apparent contradictions. However, this moment of intelligence is not sufficient to act upon the world because the synthesis it proposes can be contested and, by definition, negated anew: If the world is only dialectically interpreted, it may become an interminable process in which everything turns negative and positive alternatively, any synthesis being an ephemeral plateau collapsing into a new thesis-antithesis dynamic. Dialectics tends to fall into binary dichotomies, which are themselves cognitive reductions, even if the intention is to introduce more complexity than analytic intelligence (Elbow 1993). For example, the two categories of disease and normal health are oblivious of possible alternative mental or physical states that are neither normal nor unhealthy (Canguilhem 1991, p. 97). The human phenomenon of psychological resilience is neither pathological nor normal: It is a “novelty,” a manifestation of crealectic intelligence (de Miranda 2019).

Social reality is polysemantic and implies a multiplicity of decisions and acts in which the very factualization of data, the attribution of a syntax to a given reality, are already filtered by creative and active imagination (see ► “Imagination”) and an embodied perspective. Crealectics aims at describing the form of consciousness that is aware of acting as an engaged and unified person upon a world of multiplicity with the ideal of cocreation in mind.

Crealectic intelligence transcends the borders of the actual and of the Real and, therefore, is related to the experience of sublimity. Artists have known or felt for long enough that creativity as ultimate principle is a relationship with the intuitions of alterity, of wholeness, and of the sublime, “the incommensurability of reality to concept” (Lyotard 1984, p. 79). Even for non-artistic practitioners, the experience of the sublime, for instance, in contemplating nature or in confronting a new culture, manifests itself as surreal or hyperreal awe, beyond the analytic routines: “Sublimity lifts the Absolute above every immediate existent and therefore brings about the liberation which, though abstract at first, is at least the foundation of the spirit” (Hegel 1835, p. 362).

Sublime feeling sensitizes us to an “outside and an inside” in thought, to a creative “hyper-dialectic” between imagination, reason, flesh, plurality, and ambiguity (Merleau-Ponty 1968, p. 94). Within the crealectic approach, healthy human life and healthy thought need to host regular moments of felt sublimity, as a necessary condition to reconnect with the possibility of regeneration or novelty. The intuition of creal sublimity, the possible as absolute, becomes “the transport that leads all thought (critical thought included) to its limits” (Lyotard 1994, x). This paradoxical capacity to pursue belief or knowledge about something we typically ignore, but feel or desire to be real, can be productive of new knowledge and new forms of dealing with existence: It suggests the effectual agency of what Einstein called “creative imagination” (Holton 1978, p. 96). Notoriously, Einstein was often daydreaming about the possible in order to actualize new forms of understanding nature, space, and time.

Crealectics and the Possible

In remaining open to the “creative generosity” of life (Canguilhem 1991, p. 188), the democratization of crealectic intelligence may allow for a new form of global consciousness, one that would expand the domains, diversity, and agency of the possible (see ► “Possible in Philosophy”). Crealectics is a program of harmonization of our capacity to feel, imagine, envision, realize, and actualize a world emerging from the cosmological source of the Real as a metaphysical “possibility of possibility” (Slife 1994). Crealectic intelligence deals with processing realities and imaginaries of novelty and plurality rather than mere contradiction of binary polarities or analytic operation of known bits; its ontological core is the philosophical idea of creation understood ontologically as a ubiquitous stream of absolute possibility (Bergson 1911; Whitehead 1929; Deleuze and Guattari 1994; de Miranda 2017). We may think of the crealectic emotion as the opposite of depression. In the latter experience, one may feel like the earth is an empty rock, devoid of anything

but cardboard illusions. In the crealectic experience of the world, we are not looking at reality as a source but as a compossible manifestation and interpretation among many others of *creality*, a source of infinite abundance of possibility.

As was understood by existentialist philosophers, chief among them Sartre and Heidegger, the universe is a possibilization furnace. The simultaneously immanent and transcendent – “transimmanent” (Nancy 1996, p. 48) – ground of ever-emerging possibilization (*Ermöglichung*) is conceived as *opening for the making-possible* (Heidegger 1995, p. 364; 1996, p. 244). This cosmological opening may be summarized in a simple modal formula: “It is possible,” where *It* designates the ultimate being-becoming (de Miranda 2020a). “There is a practical consciousness, an ‘I can’ that underlies and precedes the reflective self-consciousness of the ‘I think’, but the ‘I can’ is given and coeval with an ‘it can’” (Sinclair 2017, p. 191). The Surrealists, for instance, trusted this source of creation when they produced their works of art based on letting go of the obsession of controlling consciousness analytically.

When one embodied living being says and feels, of a projected situation or idea, for instance, that *it is possible*, they are connecting with the modal creal spacetime. The embodied formula is – at least asymptotically – performative: It begins to produce something, it is the gateway to transform a virtuality into a reality, and it *possibilizes* or “*crealectizes*” (de Miranda 2020a). The felt experience of possibility creates a bridge between the imaginary and the real. Human instances of this generative feeling abound: Think of any founder slowly manifesting, day after day, the metamorphosis and growth of an impression or ideal into a real space of experience.

In other words, as argued by Bergson, the possible is not a deterministic program contained in the past, but rather continuous participative co-creation, or “organic possibility” (Gunter 2007, p. 38): “This extensive continuum expresses the solidarity of all possible standpoints throughout the whole process of the world” (Whitehead 1929, p. 103). In order to express the interdependence not only of all things but also of the physical, the

psychological, and the spiritual realms, the crealectic approach distinguishes three modes of possibility which correspond to the three types of intelligence we have evidenced: the *physical possible*, the *psychological possible*, and the *philosophical possible*. The physical possible relates to conditions toward the analytic realization of discretizable things via material causality. The psychological possible relates to the dialectic realm and its movements of tensions, dualities, and degrees of liberty or alterity. The third mode, the philosophical possible, originates in the crealectic intelligence process, by which thought as a spiritual property of the universe transmutes (into) the other two possibles. Attempts at explaining how this transmutation might be brought about constitute the history of philosophy itself, from Plato to Hegel et al., from hermeticism to process philosophy. For a crealectician, philosophy is not the mere logical analysis of truth conditions, but the self-questioning enterprise of thought regarding its own possibilizing and world-making power. Thought, desire, persistence are performative; crealectic intelligence is generative.

Summary

The term “crealectics,” coined by philosopher and author Luis de Miranda (2017), is a compound of “Creal” (from “creative” and “Real”) and of two possible suffixes: “logos” (from the Greek word designating a universalized meaning) or “ektos” (from the Greek root meaning “toward the outside,” “outer,” or “external”). Crealectics addresses the intuitive way through which we unify realities and imaginaries of novelty, plurality, and ambiguity, in a cocreative manner rather than via mere contradiction of binary polarities or analytic operation of known bits. The ontological core of crealectics, the Creal, is the idea of creation understood ontologically as a ubiquitous and transimmanent stream of absolute possibility. The crealectic frame posits that there are three complementary and effectual domains of intelligence, namely analytic, dialectic, and crealectic, being alternatively or complementarily used in human

interaction with the world. The objects of crealectic intelligence are the relative possibilization and realization of absolute possibility, the becoming real, biological, and social of creation, and the multimodal externalization and asymptotic unification of an axiomatic creative flux, via three realms of possibilization, physical, psychological, and philosophical.

Creating the Future

Arran Gare

Philosophy and Cultural Inquiry, Swinburne University, Melbourne, VIC, Australia

Abstract

“Creating the future” is a notion introduced by Alfred North Whitehead to define the task of universities and the function of philosophy. Implicitly, it is a rejection of the idea that the future is already determined and, in some sense, already exists as part of a block universe, with the appearance of temporal becoming an illusion. “Creation” originally meant “the action of causing to exist” or “a coming

into being.” The “future” is not normally considered to be what can be created. Originally, it meant “yet to be.” It now tends to be defined in relation to time, as “the time to come,” where “time” is assumed to be an independent existent along with space as the “containers” of material beings, with the future in some sense preexisting its becoming present. The quantity of “matter” or “mass-energy” is assumed to be constant and to change its position and configurations in predictable ways over time. To refer to the future as being created is to reject this view of the universe and the basic concepts that define it, replacing these with concepts that can make intelligible the freedom of and creativity of people, the future as in process of being created, and humans as partially responsible for what future is created. It is to recognize that there are real possibilities that can be envisioned, understood, chosen, and brought into existence, with some of Whitehead’s followers claiming that new possibilities can also be created.

Historical Context

“The task of a university,” wrote Alfred North Whitehead in the epilogue to his book *Modes of Thought* (1938, p. 171), “is the creation of the future, so far as rational thought, and civilized modes of appreciation, can affect the issue. The future is big with every possibility of achievement and tragedy.” This proclamation, while appearing simple, is founded on a speculative philosophical system that challenges and attempts to replace assumptions that have dominated science and the broader culture since the seventeenth century. From the perspective of scientific materialism originating at that time, there is no creation, except possibly an original creative act by God in creating the universe with all its components and laws of motion. It was a conception of the universe consisting of inert matter moving

endlessly, meaninglessly according to immutable laws, and the success of science was defined in terms of how everything else that appeared or happened in the world could be explained as merely the effects of these laws of motion. It was essentially a deterministic, block universe. While science has moved beyond this conception of the universe in detail, giving a place to a diversity of elementary particles and forces and to energy and information, mainstream science is still dominated by assumptions put in place by Newton, requiring of explanations the construction of mathematical models that map out all possible states of a system and show which possible states must necessarily have been or will be, given boundary conditions and the current state. Possible states are mere mathematical constructs for specifying what is in the present, what has been in the past, and what must necessarily be in the future. Including some indeterminacy in these models and accepting probabilities accords more significance to possible states, but not much more.

From this perspective, living beings, including humans, are complex machines, and free will is an illusion, even if some indeterminacy is acknowledged. Organisms survive because their structure ensures that they operate to maintain and reproduce themselves in competition with other living beings or, perhaps as Richard Dawkins argued, reproduce their genes. As Thomas Hobbes (1982, p. 113) argued, thinking ultimately is nothing but adding and subtracting, and science is knowledge of how to control the world to satisfy appetites and avoid aversions, most importantly death. The most important additions to this cosmology since Hobbes as far as characterizing life and mind are concerned have been Darwinian evolutionary theory and the addition of information to what exists (along with matter and energy and forces of attraction and repulsion), equated to negative entropy. DNA, making up our genes and determining our adult form, encodes information. The brain processes information just as computers do. Modern science, characterizing living beings as information-processing cybernetic machines and explaining human interactions through game theory and economic models, upholds a Hobbesian/Darwinian worldview.

While this cosmology provoked a reaction from philosophers defending the reality of consciousness, free will, and grounds for ethical action transcending egoism, even Immanuel Kant and Friedrich Schelling who were most concerned to defend the reality of freedom still accepted a deterministic universe. Such determinism was challenged by Henri Bergson who argued that there is an asymmetry between the present and the past and the present and the future. In *Creative Evolution* (1983), he argued that the future, while influenced by the past, is open and that genuine creation, not entirely determined by the past and not simply random, is possible. In *Process and Reality* (1978), Whitehead developed a speculative cosmology based on advances in logic and the sciences that would rigorously defend this view of the universe. Identifying, questioning, and rejecting deep assumptions that had dominated thinking since the Ancient Greeks and had crystalized with scientific materialism, most importantly the notion “substance,” Whitehead developed a categorical scheme that made “creativity” the first category of the “ultimate,” the most basic category through which all that exists are defined.

What this means is that Whitehead was rejecting the idea that there is some “substance” – “matter” or whatever – that is moving, rearranging, or reorganizing predictably over time, arguing that the universe consists of “organisms” understood as self-creating processes. What exist first of all are “actual occasions,” the being of which is constituted by their becoming. These elementary organisms do not exist in isolation but only become only through relating to past and contemporary processes. They are constrained by these, but not completely determined by them. They are capable of and do form into “societies,” which are more complex “organisms.” In Whitehead’s categorical scheme, there are also “pure potentials” or possibilities, characterized as “forms of definiteness,” which can be selected and realized as “ingredients” in these creative processes of becoming. Originally, Whitehead referred to these potentialities as “eternal objects” but, later, dropped this term. Later philosophers inspired by Whitehead’s philosophy argued that, with the evolution of the universe, new possibilities come into existence (Code 2002).

It is in terms of this philosophy that Whitehead developed his notion of creating the future, defending the reality of human freedom, and characterized universities as participating in creating the future.

What Is “Creating the Future?”

Given Whitehead’s characterization of universities and philosophy as playing a role in creating the future, developing the notion of “creating the future” is itself participating in creating the future and illustrates what it involves. In *Modes of Thought* (1932), Whitehead railed against philosophers who worked within the limits of the dictionary on the assumption that humankind has already entertained all the ideas required to elucidate experience. It is here that he defended philosophy as “an attitude of mind towards doctrines ignorantly entertained.” He continued, “The philosophic attempt takes every word, and every phrase, in the verbal expression of thought, and asks, What does it mean?” (p. 171f). To overcome the limitations of language, words must be defined and redefined. As he wrote in *Process and Reality* (1978, p. 4), “Words and phrases must be stretched towards a generality foreign to their ordinary usage; and however such elements of language be stabilized as technicalities, they remain metaphors mutely appealing for an imaginative leap.”

In stretching words, it is clearly necessary to assume that they have some meaning before they are stretched. The words “creating” and “future” have common sense meanings, although these are not entirely clear and they have altered over time, and both are more limited than implied by Whitehead’s use of these words. With our positivistic understanding of science and technology, which Whitehead and his allies have been concerned to oppose, “creating” is accorded little place. Advances in science are taken to be the outcome of investments employing trained people to apply the scientific method to accumulating knowledge, which now can be equated with information, with metrics being developed to measure efficiency in its production. Evolutionary epistemology characterizes this as a further rearrangement of matter,

energy, and information in the struggle of cyborgs for survival and domination, which with enough knowledge could be explained and, in principle, predicted. “Creation” has been accorded a greater place in the arts and humanities. This is associated with the celebration of writers and artists who produce something entirely different than has ever been produced before. However, this trivializes this area of culture (and creativity), which, as Hobbes (1982, p. 102) argued, should be regarded as amusements and nothing else. This view of the arts and, along with the arts, the humanities has engendered fashions changing at ever faster rates, without any evidence of progress. Only science and technology facilitating more efficient control are recognized as achieving and contributing to progress. In placing rational thought and civilized modes of appreciation at the center of creating the future, Whitehead was rebelling against such thinking, portraying the great advances of science and technology along with the arts and humanities as major creative achievements.

It was in carrying through this rebellion that Whitehead made “creating” central to his speculative cosmology. The coming into being of elementary particles, galaxies, and stars with planets were essentially creations, as were the emergence of life on Earth, ecosystems, multicelled organisms, animals, and humans. Creation is also evident within these created processes, for instance, in the development of embryos into fully functioning organisms and human newborns into cultured individuals able to participate responsibly in social and cultural life. While scientific materialists attempt to explain away such creative developments, for instance, by explaining epigenesis in organisms as simply control by DNA of biochemical reactions, scientists influenced by Whitehead see such developments as deeply problematic for mainstream science.

It is not just a matter of having to accept the reality of emergence. “Emergence” names a problem, not a solution, especially when considering the emergence of sentient life and consciousness. Construing being itself as essentially creative was Whitehead’s solution to the problem of emergence (Gare 2002). New self-stabilizing patterns or “organisms” coming into existence, some radically different from the conditions of their

emergence but dependent upon them, were made intelligible by Whitehead through giving a place to creative self-formation of “organisms.” As actual occasions or societies of actual occasions, these “organisms” can realize entirely new possibilities or, as Whitehead characterized them, new forms of definiteness. These in turn make possible further creative emergence, creating further possibilities. The formation of the solar system created a planet that provided the conditions or possibility for the emergence of life. Primitive life made possible the emergence of sentient beings, then conscious beings, and then humans with language and then specialized discourses and institutions of learning, leading to the emergence of philosophy, mathematics, science, and literature. In this way, the possibility was created for philosophers to develop their understanding of the cosmos and to become conscious of its creativity and of their own work as participation in its creation.

Rejecting the Newtonian conception of time as an independently existing actual entity, Whitehead (1978, p. 320) argued that the past and the future must be defined in relation to the duration of actual occasions and causal efficacy. The past is that which present actual occasions are responding to, while the future is that which these actual occasions can causally influence. There is not only one duration but also a multiplicity of interrelated durations. Diverse actual occasions create the continuity of extension, which is the most general form of connectedness between them. Extension is real, because relations are real, but it is not actual but potential. As Whitehead (p. 66) put it, “[t]his extensive continuum expresses the solidarity of all possible standpoints throughout the world; it is the first determination of order – that is, of real potentiality – arising out of the general character of the world.” Space and time are aspects of this extensive continuum, an order of potentialities for independence and interaction created by durational processes which, as processes of becoming, are creating space and time. Space and time are not the preexisting containers of durational processes but are themselves created relations that, as ordered patterns of potentialities, become components of these processes.

Universities and Philosophy in the Context of Creative Evolution

As conceived through more recent Whiteheadian cosmology, the evolution of the universe, life, and humanity have generated an increasing range of new possibilities and capacities to explore and embrace these. It took a billion years for eukaryotic cells that could combine to form complex multicelled organisms to evolve from primitive life. It took several 100,000 years for *Homo sapiens* to develop civilizations, making possible the development of literacy and educational institutions, providing the conditions for the development of rhetoric, history, mathematics, and philosophy. It took 2000 years before history, mathematics, and philosophy engendered experimental science. In each case, new possibilities were generated and embraced. The nature of this emergence is evident in the sequence of life forms. Plants have possibilities for altering their conditions of survival by being able to grow toward light and send roots down to water and produce chemicals to deter parasites. A sequence of new possibilities opened with animals being able to move. A snake responds to its immediate perceptual field and will pursue a mouse, but if the mouse disappears, the snake will cease pursuit. If a cat is pursuing a mouse and the mouse disappears, it will continue pursuing the mouse. Its cognition extends to what is not immediately present in its perceptual field. Humans through language can consciously develop their cognition over generations, enabling them to develop their comprehension of the entire universe and its history and envisage possibilities that have never existed.

This capacity was greatly augmented through the development of history, mathematics, and philosophy and then experimental science and the institutions to advance these. New scientific theories not only explain what is but also reveal new possibilities. Thermodynamics postulates absolute zero Kelvin (K) at -273°C as the lowest possible temperature. The universe is cooling so that outer space is now 2.7°K . Humans have now been able to cool helium down to very close to 0°K , which, unless there are other intelligent beings in the universe, is a temperature that has

never existed before. This could open up the possibilities of new forms of technology exploiting superconductivity or superfluidity, just as Maxwell's explanation of light as a propagating wave of electromagnetic fields enabled Hertz to discover radio waves, ushering in a sequence of new forms of electronic media and other forms of technology, opening new possibilities for communication and organization of societies.

Such technological advances most clearly manifest the role of rational thought in creating the future. However, Whitehead was also concerned to defend the role of civilized modes of appreciation. Predicting the possible consequences of actions, including such technological developments, and evaluating these and then choosing to avoid paths heading to disaster are far more difficult. History is one of the most important disciplines in this regard. History originated in Ancient Greece as *istoria*, learning through inquiry into the causes and consequences of conflicts (exemplified by Thucydides' *History of the Peloponnesian War*), and then acquired a broader meaning, eventually becoming what we now understand as history. History is central to all intellectual endeavors and all complex human actions, from building a house to creating a civilization, since history is required to comprehend what has been achieved in the past, what is the present situation, what are the unfinished projects, and what are their problems. History is required to situate each agent, whether individual or organization, in the context of these projects and problems, and therefore to reveal what is required to advance these projects. The development of advanced mathematics, philosophy and science would not be possible without their history. Without history, disciplines fragment into fashions. History is also required to evaluate such developments and projects and to identify their goals, their trajectories, and their unintended consequences. In a major and very influential work of history, Whitehead in *Science and the Modern World* (1932) portrayed the scientific revolution of the seventeenth century as a triumph of the achievements and potential of mathematics, combined with developments in natural philosophy that

revealed the possibility of advancing knowledge through performing experiments, seen at the time in the broader context of fulfilling God's role for humans on Earth, showing how it led to the industrial revolution. This in turn led to undreamt of affluence, the triumph of European imperialism, increasingly destructive wars, the development of nuclear weapons capable of destroying civilization, a population explosion and the destabilization of the global ecosystem through the production of greenhouse gases, and the destruction of local ecosystems that now threaten the future of humanity.

It is in this context that Whitehead's claim for the role of philosophy in creating the future should be understood. For Whitehead, philosophy is not one discipline among others, but the discipline that puts all specialist areas of enquiry, including history, mathematics, the different disciplines within science and the arts, into perspective. Striving to achieve a coherent, comprehensive understanding of the cosmos and its history and our place within it, philosophy questions the assumptions of specialists and reveals alternative research programs while acknowledging that full understanding can only be approached and never finally achieved. Striving for self-understanding, philosophy defines what humans are in all their complexity as individuals; as members of communities, institutions and civilizations; as a species; and as a form of life. It has the task of revealing the possibilities for achievement and destruction in all of these and the responsibility of each individual participant. It is part of human self-creation. It is on this understanding that Whitehead could characterize the task of a university as the creation of the future and then portray philosophy as central to this.

Life and the Future of Civilization

Reflecting on the history of philosophy in relation to the scientific revolution of the seventeenth century and its consequences, in *Science and the Modern World* (1932, p. x), Whitehead portrayed philosophy as follows:

... the most effective of all the intellectual pursuits. ... It is the architect of the buildings of the spirit, and it is also their solvent:- and the spiritual precedes the material. Philosophy works slowly. Thoughts lie dormant for ages; and then, almost suddenly as it were, mankind finds that they have embodied themselves in institutions.

This claim was defended in the broader perspective of the whole history of European civilization in *Adventures of Ideas* (1933). The last part of this book was devoted to characterizing civilization conceived as the realization of human potential as the ultimate goal of humanity.

Whitehead's philosophy was designed to advance civilization by addressing and overcoming the basic flaws in the culture of modernity engendered by the scientific revolution. He was principally concerned to challenge positivist theories of knowledge and replace scientific materialism, overcoming the division in modern civilization between science and the humanities and all the problems engendered by this division. This involved a new understanding of nature and of life, reinterpreting recent advances in physics, and making intelligible the emergence of subjects and consciousness within nature. The most important group of people inspired by Whitehead were not professional philosophers but scientists; however, these scientists embraced Whitehead's grand vision for philosophy and its role in science and civilization and contributed to developing this philosophy. To begin with, Whitehead's main influence was on biologists, notably the theoretical biology movement led by C. H. Waddington and Joseph Needham.

The theoretical biology movement was opposed to the reductionism of biochemists and orthodox Darwinists and focused on embryology and epigenesis. The problem in embryology is to explain how cells dividing and multiplying differentiate and generate the complex forms of adult organisms. Inspired by Whitehead, Waddington characterized this as a self-causing process developing on necessary paths, or chreods, through individuation engendering subprocesses and sub-subprocesses, etc., associated with specific organs and their components. These necessary paths are self-stabilizing and, if development is deflected,

will return to their paths. However, these processes can become unstable and switch to different paths or be captured by other processes. DNA plays a role in influencing these paths of development and which paths will be taken but should be seen as encoded instructions to be utilized by the developing organism rather than the organism being determined by it, without any simple one-to-one correlation between DNA and the phenotype or adult organism. Also, which paths are taken can be in response to the environment of the developing organism. That is, while these necessary paths imply some predictability in patterns of development in nature, there are other possible paths that could and, under certain circumstances, would be taken. While developed to characterize the processes of embryology, Waddington believed these concepts could be generalized to characterize developments elsewhere, including developments in ecosystems, cognition (supporting the work of Jean Piaget), and human societies. Formalized mathematically by René Thom as catastrophe theory, others extended these ideas even further. Catastrophe theory has been utilized in physics, chemistry and biology, in the study of animal behaviour, in sociology and economics, in the study of politics and public opinion, and in psychology.

Waddington's colleague, Joseph Needham, became an historian of science and a sinologist. His massive study *Science and Civilization in China* (1954–2015) examined the different trajectories of Western and Chinese science in the context of the histories of these different civilizations. Whitehead had argued that his thought was more in accordance with Eastern than Western thought, and Needham took Whitehead's organic philosophy as a key to understanding Chinese thought, showing that through the influence of Chinese thought on Leibniz and the influence of Leibniz on Whitehead, Whitehead's philosophy was influenced by Chinese thought. He argued that the Song Dynasty neo-Confucian Zhu Xi, who had integrated Daoist and Buddhist ideas into Confucian philosophy, with his concepts of *qi* (energy) and *li* (pattern) had anticipated the modern scientific view that nature consists of patterns or energy developing on different paths. Applied

to civilizations and to the development of science, Needham was showing that very different paths could be taken by humanity, and science itself could develop in different ways, although he claimed that the synthesis of Chinese thought with Western science being developed by the tradition that Whitehead was advancing was superior to all previous science.

Considering the “requisites for social progress,” in *Science and the Modern World* (1932, p. 244), Whitehead identified the main threats to such progress: “The two evils are: one, the ignorance of the true relation of each organism to its environment; and, the other, the habit of ignoring the intrinsic worth of the environment which must be allowed its weight in any consideration of final ends.” Waddington was one of the early followers of Whitehead to focus on the problem of environmental destruction and sought to work out what humans could do to prevent this. Embracing Whitehead’s claim that we are creating the future, his reflections on this were published as his last book *The Man-Made Future* (1978). Here, he showed how the concepts he was developing could be applied to dealing with these problems. Lao Tzu (n.d.) is attributed the observation that “Unless you change direction, you are likely to end up where you are going.” With scientific materialism, there was no possibility of changing paths. Humans, as survival machines for DNA, will act predictably in their own interests, with some immediate concern for other members of their species sharing their DNA but no ability to work for the common good of humanity or life, making the trajectory we are on unavoidable. The Whiteheadian-inspired science of Waddington, along with Needham’s sinology, reveals the possibility of taking a different path. Ecological economics, also strongly influenced by Whitehead through the work of Herman Daly and John Cobb Jr. (1994), shows how economic institutions can be developed to ensure the economy serves the common good of humanity, understood as communities of communities, and prevent ecological destruction.

In 2007, the Chinese government was convinced by environmentalists that ecological destruction, including global warming, would be

disastrous for the future of China and for the world. Pan Yue, the vice minister of China’s State Environmental Protection Administration, argued that since Chinese would be worse affected than other people, China needed to lead the world in creating a global ecological civilization. The government embraced the goal of ecological civilization, although not necessarily in the radical form envisaged by Pan Yue and his allies. Philosophers, economists, ecologists, and other scientists around the world influenced by Whitehead embraced and promoted this goal for the whole of humanity. They are claiming we are not condemned by human nature to continue on our present path of ecological destruction to increase our own immediate affluence and to win out in power struggles at the expense of our common future. There are real possibilities, yet unrealized, for creating a world order committed to augmenting the conditions for life and humanity, including the life of the global ecosystem of which human communities are part (Gare 2010).

Summary: Creating the Future and the Possible

Defining the task of a university as creating the future was not merely rhetoric on the part of Whitehead. It was spelling out the implications of a cosmology that he had presented and defended as the basis for understanding and advancing recent developments in science and redefining nature and life and the place of humanity within nature. This was presented as part of the effort to overcome the dualisms afflicting modern civilization where the scientific revolution of the seventeenth century had rendered sentient life and mind unintelligible, resulting in an irreconcilable division between the sciences and the humanities. While the humanities originated in the Florentine Renaissance with the quest to inspire people to defend their liberty, take responsibility for their actions, and realize their potential to govern themselves, science rendered the notion of responsibility an illusion. Knowledge was seen as the means to make predictions and to control nature and people efficiently, and the drive for this

efficiency was explained through people's appetites and aversions, being themselves products of arrangements of matter that had survived against rivals because of this drive. In the conflict between the sciences and the humanities, the humanities were already facing defeat in the early part of the twentieth century when Whitehead was developing his philosophy. Whitehead's cosmology was not only a defense of the humanities through aligning science with it but also a clarification of its aims, identifying these with the advance of civilized modes of thought and civilization itself. Drawing on the entire past of European civilization while stretching words to create new meanings, Whitehead's philosophy was itself an instance of the creative advance of civilization, enabling this creativity to be understood. By encapsulating its implications in the phrase "creating the future" to redefine the function of the university, he was helping to create the future.

In mounting this defense of civilization, Whitehead accorded a central place not only to creativity but also to potentialities or possibilities. Scientific materialists accorded a place to possibilities only as means to represent what is the current state of matter and what necessarily must have happened in the past and will happen in the future. Without major revision, scientists could also allow that without detailed knowledge, it is necessary to be satisfied with making predictions of probabilities or even allow that basic laws of physics are not entirely deterministic. In these cases, possibilities are accorded some significance and even ontological status but are accorded no causal efficacy. For Whitehead, possibilities are ingredients in the elementary beings of the universe and its basic "organisms" or processes, and their role is accentuated with the more complex processes of life (what have come to be known as "anticipatory systems"). With evolution, possibilities grasped as potentialities have become increasingly important aspects of agency. With humans, rational modes of thought have greatly increased the potentialities of humans to transform their worlds. However, these potentialities can be destroyed as innovations can take on a life of their own as people become addicted to the short-term benefits they provide, either satisfaction

of their appetites or power over others. It is science as the quest for understanding beyond being an instrument for developing technology, along with civilized modes of appreciation cultivated by the arts and humanities, that humans through their educational institutions can come to appreciate their role in creating the future, revealing new possibilities, and judging which possibilities should be aspired to and thereby incorporated into projects. The importance of recognizing this has become manifestly evident in the face of the global ecological crisis, and people inspired by Whitehead are striving to reveal the possibility of and to create a new kind of civilization based on affirming the value of life and a commitment to augmenting life, not only contemplatively but also in practice. Universities are central to this task.

Keywords

Cognition · Creativity · Possibility · Thinking

Definition

Creativity is a complex phenomenon which necessitates a vast array of methods for us to understand its various segments. As a relatively young discipline, it is in constant evolution with new emerging fields of study including the possible. Cognition involves the process of acquiring knowledge and making sense of things through learning, experience, and the senses. From the point of view of creativity, these aspects merit attention and further exploration. “Creative cognition can be understood as a set of cognitive processes that support the generation of novel and useful ideas” (Beatty et al. 2016: 87). Cognitive processes support creative production through creative cognition. Ward and Kolomyts (2019) affirm that the generation of complex concepts and outcomes in a cumulative way is unique to humans. We are able to think in a wide variety of different contexts and in complex ways. These are key features that distinguish us from other animal species.

In line with many definitions of creativity, creative cognition elucidates how basic mental processes make use of stored knowledge to provide novel and effective solutions (Runco and Jaeger 2012) that are also appropriate to the task. Another dimension to the definition of creativity emerged more recently from the area of the unexpected, namely, the element of surprise (Glăveanu 2021; Ross and Webb 2022; Simonton 2012). While it is sometimes argued that such approaches reflect innate creative genius, through the creative cognition approach it is postulated that these qualities are available to all without distinction and are based on cognitive operations that (while affected by individual differences) can be performed by all (Ward et al. 1999).

Initially, two main categories of cognitive processes underlying creativity were identified by Guilford (1968); divergent thinking and transformative abilities. Guilford stipulated that while divergent thinking encourages thinking in different directions (like when we generate alternate uses for everyday objects) by implication, transformative abilities require individuals to engage with new patterns of thinking to generate new ideas and thus, break out of old configurations. This notion of transformative abilities implies that our perception of the world may shape the ideas we generate.

Due to the adoption of different perspectives, to date scholars have not yet pinned down a single comprehensive conceptual framework to address creative cognition. However, it must be noted that similarities between different models exist. For instance, Finke et al. (1992) developed the Geneplore model of creativity which was more intended as a descriptive model rather than an explanatory theory of creativity. The term Geneplore combines the terms generate and explore. The authors claim that creative activity takes place when we first generate new ideas and then explore their possibilities and suitability. This mental process seems to stimulate creative thinking. Exploring the Geneplore model, one finds three main components; generation of pre-inventive structures, preinventive exploration, and interpretation and product constraints. The generation of preinventive structures is constructed during the initial stages of the process.

Interpretation of these structures takes place during an exploratory phase where the focus or expansion of the concept being explored may take place. The emerging insights are then directed to defined problems or else they may also be elaborated on through the modification of the initial preinventive structures and a repetition of the cycle. Constraints on the process may be applied at any time. Although this model is similar to Guilford's cognitive framework because of its emphasis on both divergent and convergent modes of thinking, the Geneplore model offers more depth through the explicit use of the five steps: generative process, preinventive structure, preinventive properties, exploratory processes, and product constraints.

Runco and Chand (1995) designed a two-tier model of creative cognition. This model includes three main components, namely, problem finding, ideation, and evaluation. These core components share similarities with the Geneplore model. Runco and Chand, however, elaborate on their model by including a second tier explicating the role of knowledge which can be procedural or declarative, and motivation which in turn can be intrinsic or extrinsic. The authors take into consideration the relationship that knowledge and motivation may have on each other and on the core components.

The Importance of Prior Knowledge

Knowledge in all its forms whether declarative, factual information, or procedural (Runco and Chand 1995)) plays an important role in creative cognition. Eskin et al. (2018) support the idea that creative cognition may be influenced through the combination of existing ideas and existing knowledge. Knowledge as an important part of creative cognition is at times overlooked owing to the myth that creativity is somehow linked with a thunderbolt of inspiration. For example, Diakidoy and Phtiaka (2002) found that teachers did not link knowledge to creativity and therefore did not attribute its importance to the creative process. In many instances, past knowledge is used to generate new ideas. Ormerod and MacGregor

(2017) support this notion through their work exploring how transfer of knowledge is manifested in creative problem solving. Weisberg (1995) identified instances where subjects used information that was previously used in another situation and transferred it to a new context. This implies that existing knowledge is also important for combinatorial processes where old knowledge may lead to the creation of new concepts and new information (Simonton, 2022).

It is important to observe that knowledge is not used in isolation. In their mission to understand and enhance creative mental processes further, Finke et al. (1992) developed the creative cognition approach with the aim of understanding how human minds produce creative ideas. This approach supports the idea that knowledge may play a role in creativity. This can possibly take place through analogical or spontaneous transfer. Analogical transfer takes place when similarities between problems lead to the application of a solution previously used to a new problem. On the other hand, spontaneous transfer takes place when a source of information is considered relevant and applied without prompting. In this case, similarities are not compared or evaluated (Ormerod and MacGregor 2017).

Further work was carried out by Benedek and Fink (2019), who developed a neurocognitive framework of creative cognition explicating the roles of memory, attention, and cognitive control. The authors argue for the need to refine and further define the role of the functions that make up neurocognitive functions like memory, attention, and cognitive control. Focusing on the functions that make up creative cognition and using up-to-date evidence from research, the authors harnessed constructive memory processes which are involved in the building of new representations, directed attention which supports active imagination and the implementation of goal-directed memory and attention processes through executive control to formulate a new neurocognitive framework of creative cognition. These later developments in the theorizing of creative cognition remove the explicit focus that was typically placed on the generative and convergent aspects of creative processes and

shifted attention to the roles harnessed by memory, attention, and cognitive control that individuals engage with when thinking creatively.

Research on Creative Cognition

Various researchers have explored how the human brain works when engaged in creative activity. The use of existing knowledge and of conceptual notions in the process of creative cognition has been studied initially from a cognitive psychology perspective. A hallmark piece is the work by Ward (1994) who had asked students studying psychology to imagine life on other planets. The students were instructed to draw and describe a species of animal that might live on these planets. Most students produced illustrations that included eyes and limbs that offered a symmetric appearance. These outputs appear to be highly influenced by previous knowledge that the students had and perhaps assumptions that are made when asked to draw “animals”. In this and other similar studies, the different levels of abstraction have been used to differentiate between creative and non-creative cognition. Individuals who did not manifest cognitive flexibility, and who could not free themselves beyond the basic level of abstraction, for instance, offered non-creative cognitive outcomes by keeping to similar shapes and proportions in their illustrations.

More recently, using different research methods, Beaty et al. (2014) explored how the mind produces creative ideas. The researchers studied how executive and associative processes influence creative thinking. Their research found that increasing the semantic distance between verbal fluency responses and cues resulted in enhanced quality of divergent thinking. Previous research had mainly focused on either executive or associative processes related to creative cognition where associative processes involve the spontaneous emergence of creative ideas resulting from associative processes that take place in semantic memory, while executive processes coordinate and regulate the flow of information processing (Brown and Braver 2009).

The project by Beaty and his colleagues indicates that both processes may stimulate the generation of new ideas. In 2016, Beaty et al. published work detailing further research in the area. They found that during creative cognition and artistic performance, the default network which is linked to episodic memory retrieval, and executive control networks work well together. This may further support the claims by Finke and colleagues suggested above that combinatorial processes are involved in creative cognition.

Strategies to Enable Creative Cognition

Creative thinking or “the thinking cap effect” as Weinberger (2020) refers to it, involves the need to deliberately think in new ways to generate new ideas or elegant solutions. Boden (2004) claims that creative thinking can be made possible by constraints, an idea that is also supported by the Geneplore model where constraints are components in the generative, exploratory, and interpretive process. This may lead to the engagement with a dual process involving the generation of ideas and the convergence of the same ideas leading to a final outcome. A variety of frameworks have been proposed to facilitate creative thinking like TRIZ (Terninko 1998), and Creative Problem Solving 6.1™ (Isaksen et al. 2011) which are highly structured. Other methods involve the use of a series of creative thinking tools to formulate thinking sequences at will. The late Prof. Edward de Bono formulated a variety of frameworks that may facilitate creative thinking through the explicit use of thinking tools. The Six Thinking Hats, Power or Perception and Lateral Thinking methods are only a few of the variety of simple techniques that may lead to higher engagement with the creative process. Lateral thinking in particular is about “possibilities and what might be” (de Bono 1992: 89). Systematic techniques like random input may facilitate the generation of new ideas through the use of unconventional thinking methods. Typically, conceptual expansion is at the heart of these creative thinking methods by facilitating

the process to make new associations and exploring problems from different points of view (Abraham 2014). Through its phases, namely, the generation of preinventive structures and the preinventive exploration and interpretation phases of the Geneplore model, similarities on how new possibilities may be conceptualized emerge.

The Importance of Cognitive Flexibility

Abraham (2014) presents a graphic representation of a process involving different mental functions that are employed when practicing creative thinking. One shortcoming of this representation relates to the emphasis on the generative aspect of the process. Convergence does not seem to be included. Notwithstanding this, the simple concept presented by Abraham indirectly introduces the notion of perspective shifting, an all-important function in the practice of creative thinking.

Perspective shifting using both associative and executive processes leading to the production of creative ideas that are novel and useful are at the heart of creative thinking. Cognitive flexibility has been shown to lead creative ideas through originality. This happens when the individual is able to manipulate the information available when thinking creatively (Ritter et al. 2014). One may conclude that creative thinking requires both Type 1 and Type 2 thinking. Type 1 thinking involves automatic responses that happen in quick succession while Type 2 thinking requires more effort and time (Evans and Stanovich 2013). This section highlights the potential that creative thinking can offer to operationalize theoretical concepts like Pro-C, little -c, and mini-c of creativity (Kaufman and Beghetto 2009). The authors suggest microgenetic methods to explore the development of creative thinking. These methods may include observations and retrospective explanations offered by participants among others. In turn, this may present opportunities to ignite creative cognition making everyday creativity (Richards 2018) real.

To this effect, from a conceptual point of view, He (2017), proposed a model indicating the processing modes of intentional creative thinking. He uses imagery thinking and intuitive thinking as the base constructs. The model is presented in a circular structure with arrows pointing in both directions indicating an interdependence between the three elements logical thinking, imaginative thinking, and intuitive thinking.

Creative Cognition and the Possible

The possible. This notion invites us to aspire, to think ahead, fantasize, and wonder. Thinking beyond the “here and now” and engaging with the “not (yet) here” (Glăveanu 2021) gives us the opportunity to imagine our futures and plan strategies to achieve goals accordingly. The concept of the possible invites us to explore, to consider, or even to design options that we may not concretely believe are realistic. This stance allows for a certain freedom of thought that may be challenging yet rewarding.

Why is the possible challenging? Breaking free of old thinking patterns is difficult. Most individuals use a convergent thinking style often associated with fixed patterns of thought (Walton 2003). This notion alone calls for action to encourage engagement with generative practices. As noted above, humans typically use combinatorial efforts to engage in creative cognition leading to novel, elegant ideas that are also useful. This view on creativity may pose limitations to our outlook to the possible. The element of appropriateness (Sternberg and Lubart 1999) in the basic definition of creativity may lead to restrictions into how broadly one may think in terms of new ideas by imposing self-judgment. Boden (2004: 41) goes a step further by claiming that creative ideas need not only be useful but also “illuminating or challenging”. This stance could be a step in the creation of possibilities. Craft et al. (2013), refer to combinatorial play as a method to steer thinking in the direction of “what might be?”

Possibility Thinking (PT) originally established by Anna Craft symbolizes a process

of generative activity. Defining PT as “the transformation from what is to what might be” (Craft and Chappell 2016), Craft started the PT movement asking “what if?” using different scenarios. This mode of engaging cognitive processes leads to the shift from “what is this and what does it do? To what can I or we do with this?” (Craft et al. 2013). This mode of thinking is open and invites contributions to the formulation of potential scenarios emerging from “what if?” Although the origins of PT lie in research in educational contexts, the concepts may be transferred to other contexts with ease, thus creating opportunities for changing mindsets, encouraging a forward-looking outlook.

More potential ways engaging creative cognition with the possible may be sought in mind-wandering. Mind-wandering “refers to those moments in which our thoughts take us away from the here and now of immediate experience and action towards unrelated ideas, images and events” (Glăveanu 2020a:85). Studies show that humans engage in mind-wandering or daydreaming at regular intervals. It would be useful to harness the power of mind-wandering to spin-off new ideas that can help humanity solve various problems that effect society. Wu and Hao (2020) claim that researchers believe that mind wandering could enable creative cognition. Breakthroughs may be achieved when associations and ideas produced by mind wanderers are collated.

Achieving the Possible Through the Cultivation of Creative Thinking

In a recent publication, Glăveanu (2020b) comments about the potential abstract notions related to “the possible”. To cultivate the possible, he suggests that we are “aware of what is possible and its exploration”. (p. 53). Everyone has creative potential (Runco 2003), how we look at things is what can make a difference in how we might shape the future. New possibilities can emerge if creativity becomes an everyday activity (Richards 2018). To this end it is important for individuals to engage with creative processes in

order to possibly extract new possibilities from everyday discomforts or necessities that might lead the way for a better society. At this stage, mind-wandering consisting of self-generated thoughts that may not be related to anything in particular (Fox and Beaty 2019), can gain relevance since through such practice, we might engage with the possible. PT may also offer suitable opportunities to explore and design the future. These can be perceived as highly empowering practices as individuals who can think creatively may have a better chance at forging their own futures.

Moving away from theoretical concepts, we may note that a variety of techniques exist that may stimulate the design of what is possible as noted above. Through his work Prof Edward de Bono proposed simple techniques to guide the practice of a forward-looking stance. PO or rather Provocative Operation is one of a set of lateral thinking techniques that can be put to use to wander and actively think about the possible. This technique engages in a dual process through a generative stage that may then be converged. One prominent feature of this thinking method that links with the possible is “Wishful Thinking”. Individuals practicing the tool are invited to explore their wishful thinking in relation to specific topics that may be generated at will. It would be interesting and potentially very useful if empirical studies had to be carried out to assess the impact of PO and similar creative thinking methods.

Conclusion

Creativity involves breaking out of established patterns in order to look at things in a different way. (de Bono 1990)

Through this brief overview, creative cognition was explored through its historical conceptions and how these may be adapted to gain an outlook on the possible. This hopeful and dynamic concept may offer opportunities for academia and society at large to take charge and design the future by focusing on the “not yet” creating space to make it happen.

Creative Development

Ross C. Anderson
University of Oregon, Eugene, OR, USA

Abstract

Creative development is the process of individual and collective growth in new, effective, and meaningful ideas, skills, thinking, and production. The creative growth of individuals can happen within a specific domain, like science, and also develop generally in skills and dispositions that are transferrable across domains. As a sociocultural process, creative development of one individual builds from and contributes to the creativity of others. Creative development across the life span relates to how a person adapts to the changing circumstances of life with agency, a resilient and growth-oriented attitude, and a sense of possibility for themselves and their world.

Keywords

Creativity · Development · Agency · Adolescence · Participatory

Introduction

Creative development is the process of individual and collective growth in new, effective, and meaningful ideas, skills, thinking, and production. The creative growth of individuals can happen within a specific domain, like science, and also develop generally in skills and dispositions that are transferrable across domains. As individuals take risks to contribute new ideas and solutions, they carry our collective potential for creative development further, often changing how we think about the world in profound ways. Therefore, it is optimal to conceptualize creative development through a number of approaches that relate to the possible – possible pasts, selves, worlds, and futures.

First, a multidimensional approach to an individual's creative resources creates an expansive set of possible *self* compositions that a person may bring to a task or challenge. Many of those resources are malleable with focused effort. Specific domains will draw on specific resources in different ways, and a person's possibilities for creative development will evolve with practice, developing the skill, strategy, and metacognition to enhance the process and output. Second, from a developmental perspective across key stages of human growth and the life span as a whole, there are domain-general creative resources that may be transferrable and adaptive to a range of contexts and domains. How a person reflects on themselves in the past as agents of their world and how they imagine themselves and the world they inhabit will play a role in their development. The possible identities explored in a lifetime converge in several meaningful ways with creative development. Third, from participatory, societal, and cultural perspectives on creativity, creative development does not occur within an individual. Rather, creative development is interactive between a creator and an audience and between the creator in the present and any

contributors to the evolution of that idea. Often, those breakthroughs and pronouncements aim at transformation in the world and an individual’s role in its reconstruction.

This entry links different perspectives on creative development to different dimensions of the possible with the aim of identifying potential pathways for future research, grounded in the possible as a field of inquiry (Glăveanu 2018). Throughout this entry, I will draw on a specific and key period of human development, adolescence, to help anchor the ideas presented. In light of the intense identity exploration underway during adolescence and its consequential nature for an individual’s later development, this period can provide insight into the links between creative development and the possible.

Creative Development Within Domains

An individual’s person-level creative resources include a variety of thinking skills, attitudinal orientations and beliefs, and behaviors (Lubart et al. 2013). Some of those resources, such as openness, imagination, and tolerance for ambiguity, are directly related to states that engage with the possible. Thinking about creative development as the composition and growth of creative resources provides a helpful multidimensional way of considering how an individual may approach a task or experience development in a domain. Though not exhaustive, Table 1 presents some general creative resources that research has identified as important to creative development and creative contributions. The debate about the domain generality and domain specificity of creativity (Baer 2015, 2016) has provided contrasting but complementary perspectives, reaching some consensus that specific creative resources are

necessary within domains and that general creative resources will support an individual’s creative development and contributions across domains.

For instance, Root-Bernstein (2003) documented the existence of polymathy, or creative achievement in multiple domains, to suggest a universality to the creative process of innovation and highlight the relationship between seemingly disparate fields, such as science and the arts. If we start at the narrowest framing of creative development, we can work to understand how the possible takes shape for an individual within a specific domain of activity, discipline, or pursuit and how that development can support the individual’s creative development and potential contributions, more generally. For example, an adolescent who has developed creative behaviors specific to guitar playing, such as routine practice, songwriting, and rhythm, will be more likely to experience greater creative development if they are more curious about the mood that different chords make when juxtaposed in a composition and more willing to take risks to play with possible, but unconventional combinations. That adolescent may be driven to find a possible musical, acoustic representation of a new complex emotional experience.

The development of creative resources within a domain can also support an individual’s healthy identity development – the discovery of possible selves is a key developmental task during adolescence. To make a commitment to a creative domain in life, such as learning an instrument and eventually joining a band, links creative development to healthy identity formation during this key stage (Barbot and Heuser 2017). Though commitment to a creative domain may seem self-limiting, in reality, those commitments are necessary to expand the possible contributions that the individual can make to the world. That deeper commitment also broadens their sense of

Creative Development, Table 1 Creative resources components

Creative behaviors	Creative thinking	Creative attitudes and beliefs
Skillful, committed, persevering, collaborative, experimental, embodied, adaptive ...	Curious, imaginative, divergent thinking, associative and metaphorical, integrative and synthesizing, mental flexibility, humorous ...	Openness, intrinsically driven, tolerance for ambiguity, boundary-breaking, growth mindset, risk-taking, self-efficacy ...

possibility and confidence to achieve an imagined future, such as playing live for an audience. The creative act of imagining a possible future for oneself, constructing a possible self, and working toward that self-actualization can itself be thought of as *life creativity* (Zittoun and de Saint-Laurent 2015).

Importantly, opportunities to engage in a creative commitment in life are not equitably available to people. The creative commitments that are possible for an individual, young or old, are embedded in and constrained by the individual's life course and historical time (Elder 1998). That life course of individuals is bound by the social, economic, and cultural factors at play that either open or close opportunities for creative exploration, development, innovation, and contributions. Certainly, a tension exists between the accessibility of opportunities for an individual and the agency of the individual to seek out, choose to act on, and pursue opportunities for creative development. For instance, research about creative polymaths illustrates how creative development in one domain, such as the arts, can feed insights and development in a completely distinct domain, such as science. Root-Bernstein (2003) provided the example of Santiago Ramon y Cajal, one of the first Nobel Prize winners in Physiology or Medicine, who attributed much of his renowned success in neuroanatomy to his avocations in photography and the visual arts. It is possible that Ramon y Cajal's choice to pursue his artistic development was just as important as his pursuits in science. In terms of creative development, though individuals may excel in a single domain, it is more often the case that their creative process develops, expands, and refines through activity in multiple domains, even if they don't reach the same levels of achievement across them.

General Creative Development Across the Life Span

Creative development across the life span relates to how a person adapts to the changing circumstances of life with a resilient, open, and growth-oriented attitude and with a sense of possibility

for themselves and their world (Carson and Runco 1999). A person's general creative development can be conceptualized as the emergence of strategic engagement of knowledge and creative resources related to the creative process. Using perspectives on lifelong learning, creative development can fit into a novice-to-expert continuum (Dreyfus and Dreyfus 1980), where individuals can be starting at the beginning stage of development, based on experience and exposure, not on years of life. From a developmental perspective, the general creative thinking process has been conceptualized with specific pieces: (a) problem finding and construction, (b) idea generation, (c) tolerance for ambiguity and risk-taking, (d) seeing failure as opportunity, and (e) being metacognitive about strengths, limitations, and strategy (Lench et al. 2015). An individual could be naturally gifted or developing at different rates and levels within each of those components of the creative process.

From that perspective, development to a point of expertise indicates a high level of both intuition and metacognitive capacities but should not be considered a static end – possibilities continue to abound because every context and domain requires different combinations of creative resources. In fact, the merging of disciplines and domains – a *transdisciplinary* perspective about the world – would mean that the possible “disciplines” to master are limitless. From a developmental stance, behaviors often begin by watching others, with ample exploration and trial and error, learning from setbacks and failures. With practice and deliberate investigation, learners reflect and develop the metacognition (Flavell 1979) about what works, when it works, and how to adapt it to new situations. Recent research suggests that creative metacognition plays a key role in how an individual will transform their creative potential into agentic and creative action (Anderson and Haney *in press*). As with any other set of knowledge, skills, and dispositions, becoming strategic with creative thinking, attitude, and behaviors depends on cumulative experiences in a variety of contexts as well as a mindset that with effort growth is possible, even when a challenge is quite difficult.

The developmental framework for creativity (Lench et al. 2015) places the most advanced level of creative development at a point of emerging expertise, suggesting the possibilities for how that high level of intuition, insight, and adaptability depend on a continued belief in one's potential to grow and adapt – expertise continues to be a means rather than an end.

Creative development as agentic. Recent research supports a model of creative behavior as agentic action, where the self-beliefs (e.g., creative self-efficacy) and values (e.g., nonconformity) that an individual carries into a task will dictate their creative effort, achievement, and development (Anderson and Haney *in press*; Karwowski and Beghetto 2018). Developmentally, if the individual has limited experience and knowledge in a task or domain, they may not feel a high agency to be creative in that task or domain unless they have been successful in something related. From a social cognitive perspective, a person's development in life is not just dependent on the level of their personal agency – their *proxy* agency is influenced by others and the environment around them (Bandura 1986, 2018). Whereas personal agency is made up of the prospective belief of success (or self-efficacy), the sense of control in the process, and the personal value of the endeavor, proxy agency includes the modeling and observations experienced vicariously through others. Theoretically, in one's creative development, these aspects of agency should matter enormously. Someone is unlikely to develop creatively if they lack the self-belief they can be successful and the value that it is worth their time and effort. They will also be limited without access and exposure to others who model that creative growth is possible and important. Agency in the risk-taking and openness that precludes creative development sets the stage for the possible. Without agency, the ideas of a possible creative self are unlikely to emerge, and sustained creative development toward that actualization remains *impossible*.

If individuals begin from a perspective that there are many possible organizations and reconstructions of the past, depending on one's perspective and framing of experiences, even (or

especially) personal histories of difficulty, challenge, and failure can be seen as empowering and agency-building. This sense of the possible emerging from reflections on the past can be a powerful mechanism to shift general beliefs about the potential for creative development. For instance, in a recent study, educators learned about the malleability and breadth of creative resources and completed hours of reflection and practice in basic creative thinking routines. Upon completing 28 h of training, teachers demonstrated very large decreases in their fixed mindset beliefs about creativity – the perception that creative capacity is trait-like and unchangeable in themselves and students (Anderson et al. 2020). Reflections on the possible in the past will influence the possible for one's creative development into the future. If past failure, for instance, is seen as diagnostic of one's limitations and hopelessness, then the risk-taking needed for creative growth will likely be limited. As early adolescent students have shared, when mistakes are seen as expressions of the unique interpretations of the individual (imagined possibilities), creative development has room to grow in the young person, especially in a social setting filled with judgment and pressure, both perceived and experienced (Anderson et al. 2019). The value placed on one's own potential for uniqueness and creative growth is deeply linked to the role of agency in what is perceived as possible in personal creative development.

Creative development in adolescence. To dig deeper into general creative development during a specific and important period of human growth, adolescence provides an opportune grounding. Research indicates that different fluctuations in creative development likely exist during the adolescent years (Barbot et al. 2016) – a period marked by highly dynamic biological and social growth (Dahl et al. 2018; Eccles and Roeser 2011). Healthy identity exploration and commitment are important and difficult developmental tasks during adolescence, and creative development can support that identity formation through at least three pathways (Barbot and Heuser 2017). Learners can solidify their identity through the creative commitments they make, such as joining

a band. Adolescent learners can use creative activities as opportunities for adaptive self-expression, such as jamming on the drums to express the common feeling of teenage angst. Creative thinking processes, including divergent idea production, may enhance the identity exploration and formation process by expanding what is perceived as possible and by being strategic about actualizing those possibilities in the present reality (Sica et al. 2017).

When looking at the development of one of the most ubiquitous domain-general skills studied in the creativity field during the tumultuous and consequential developmental period of early adolescence, this developmental approach comes into view. A recent study modeled the different groups of trajectories of divergent thinking originality that emerged from a sample of 1300 US middle school students from Grade 6 to Grade 8 (Anderson 2019). Across five measured time points, 72% of students demonstrated a low and declining development of originality. Among the other four groups, two rose and declined, one group showed no change, and a third group of 5% of the sample demonstrated consistent growth across the three pivotal early adolescent years of middle school. Compared to the normative downward trend of 72% of the sample, when the growth group began Grade 6, they showed higher levels of growth mindset about their abilities. In other words, they strongly believed in the possibility of their growth and development. Moreover, they valued social conformity less than the normative group, believing that being different than what others expected – holding firm to the possible in their own diversity – was more important than getting others to like them (Anderson 2019). Those two beliefs were key predictors of adaptive creative development, and that development contributed to students being more prepared for high school than most of their peers – higher academic, agentic, and creative outcomes at Grade 8.

Those findings resonate with other research, which indicate that a creative mindset is key to creative development (see entry on ► “Creative Mindsets”; Karwowski 2014), and unconventionality of a person has a strong link to their capacity for original ideas (Andreas et al. 2016). Put

another way, two ingredients appear to be key: (a) the willingness to make mistakes and, possibly (or likely), fail and interpret that failure as latent with growth potential and (b) the commitment to follow one’s own path, instinct, and unique expression, even when it may be unconventional in the face of others’ expectations. It is likely these strengths require just as much proxy agency as personal agency to develop in a context like school.

Though more research is needed about the conditions that support creative growth during adolescence and beyond, evidence of declines have prompted a range of explanations. Documented downward trends of divergent thinking during adolescence may be an interaction between the neurological, physiological, and social development underway, the opportunities provided in the environment, and the task used in measurement (Barbot et al. 2016). Explanations for an apparent Grade 4 slump appear through sociocultural perspectives, including (a) the effects of critical grade-to-grade transitions in school (He and Wong 2015), (b) normative effects of more strict classroom environments (Torrance 1968), (c) cultural differences, such as early emphasis on college entrance exams in China (Yi et al. 2013), and (d) socioeconomic characteristics of the students’ school and the different educational experiences those characteristics afford (Dai et al. 2012). Explanations also appear through affective and cognitive perspectives. Temporal gaps in socioemotional and cognitive control systems during adolescent development could explain different slumps in creative ideation development (Barbot and Hunter 2012). A common theme across those explanations is that they focus on the environmental and sociocultural conditions and biological growth underway. However, as articulated earlier, an alternative perspective that has begun to gain traction focuses on the social cognitive theory framing of agency, where the social, cognitive, and affective experience of self-belief – related to imagined possible selves – interact with opportunities provided in the environment. Though adolescence is unique as a developmental stage, because it sets up patterns and identity beliefs into adulthood, the

research and theory discussed here likely plays a role in creative development later in life.

Participatory and Societal Creative Development

Up to this point, this entry has focused on how the individual experiences creative development within a specific domain or, more generally, in their potential for creative thinking and behaviors. However, more recent work has begun to shift the gaze of creativity research from the individual in isolation toward the individual engaged with others and the world around them. These ideas relate to how we imagine our interactions with others and the environment in the possible worlds and futures – the social and cultural landscape of myths (Castoriadis 1987) that dictate our experiences and which we can each play a role in shaping (Glăveanu 2018). Clapp (2016) drew our attention to the evolution of an idea, in our collective development, and away from the supposed lone creator, who likely receives recognition, and sometimes fame, for having discovered and pursued the idea to the point of expression valued most societally and culturally. Often, deeply embedded collaborators may receive much less acknowledgment than the individual at the head of the idea (Glăveanu 2011). A postmortem dissection of an idea or discovery to understand the many contributing minds that produced the idea rarely happens; however, some research has looked at how an idea evolves in interdisciplinary groups, proposing a six phase process, each phase a *room for opportunity* of the possible (Ness and Søreide 2014). For instance, Ness and Søreide (2014) found that the third phase, called *polyphony*, included effort to understand and blend diverse perspectives from the different disciplines within a group, producing friction and an opening to new possibilities and learning.

The process of theatrical improvisation provides another snapshot of the collaborative process in a creative endeavor. Launched by a “golden premise,” individuals build off of an idea in the moment, using intuition, possibility thinking, and random acts, to sculpt something

new together. An improvisational piece is made up of a rapid succession of interpretations and contributions that are unique to each individual. Though often drawn out over years or generations, the passing of an idea through unique individuals, until it evolves into something demonstrably creative, is a participatory and co-generative process. If creativity is really about the evolution and passage of an idea through a cultural milieu from one person or one group to another, then creative development should not be thought of so intensely in isolation of the individual. Such a narrowing limits the possible in terms of our conception of creative development – both how we study and pursue it.

Creative development societally often begins with disruption and possibly a paradigm shift (Kuhn 1962). That revolution can happen through multiple pathways, including scientific discovery, irrational enthusiasm, disaster, or social and cultural movements, for instance. Creative development of individuals and a group, as a whole, can occur through greater means for exchange of ideas and information and cross-disciplinary collaboration (Ness and Søreide 2014). Technological advances have created a participatory culture online, where anyone with a connected device can create and contribute new content. These advances may be advantageous for one specific pathway for social and cultural creative development – specifically, the creative and artistic activism, or *artivism* (see entries on ► “[Social Change](#)”), of an individual or group aimed at shifting perception and consciousness about issues in the world around them (Glăveanu 2017).

Distinguished by the element of surprise, novelty, and potency, artistic and creative activism can seed new ideas about the world in the audience and boost the sense of possibility and purpose for the creator(s), emboldening individuals or groups with the possibility of liberation from oppressive or dominating views or conditions. When individuals or groups take creative risks (often these risks can include the risk of arrest or more), those examples are experienced vicariously by others and can boost the sense of agency in others within their own creative development and contributions. These constructed moments

can shift individual or collective views about the ingrained myths of social and political institutions, thereby releasing minds into the possibility of different worlds and futures. This socially and culturally engaged perspective on creative development expands conceptions of creative development as a phenomenon experienced in isolation by individuals into realms of interdependency, participation, and possibility.

Conclusion

Creative development and the possible are inextricably linked. At the individual and personal levels, a sense of agency and belief in growth undergirds what can be imagined in our own unique creative development. That sense of agency can act reciprocally in the collective with others by establishing new narratives about what is possible and how to seek out and actualize those possible selves, worlds, and futures in the current lives we lead.

Creative Inconclusiveness

Giovanni Emanuele Corazza

DEI-Marconi Institute for Creativity, University of Bologna, Bologna, Italy

LaPEA, Université de Paris and Univ Gustave Eiffel, Boulogne-Billancourt, France

Abstract

Creative inconclusiveness is a state of uncertainty in a creative process, one in which multiple possibilities are still open for exploration. Inconclusiveness is not an accident, rather it is a fundamental part of the creativity phenomenon that is not captured by the standard definition of creativity, but that is covered by the dynamic definition of creativity, within the theoretical dynamic creativity framework. Creativity requires going beyond the boundaries of existing knowledge to explore untested possibilities, irrespective of the fact that in doing so one might or might not be awarded a creative achievement. Intrinsic and extrinsic causes for creative inconclusiveness are discussed, as well as the conceptual extension of inconclusiveness, uncertainty, and possibility to the dynamic universal creativity process. It is shown how the response of the creative actor (s) to states of creative inconclusiveness is crucial, with highly creative individuals able to extract positive energy from the ensuing

frustration, whereas those with low creativity abandon. Six eminent examples of geniuses who experienced very significant inconclusiveness are discussed: Edison, Marconi, Jobs, Lamarck, Van Gogh, and Leonardo. Indications for future research activities on the subject of creative inconclusiveness are provided.

Creativity · Creative inconclusiveness · Dynamic creativity framework · Dynamic definition of creativity · Dynamic universal creativity process

Definition of Creative Inconclusiveness

By definition, conclusive evidence is interpreted as a definitive and certain result that leads an action to an end. The emergence of conclusive evidence therefore justifies the termination of a process, closing any further possibility, eliciting what can be identified as a state of conclusiveness. Conversely, inconclusiveness is a state or condition which is the antonym of conclusive: a state of uncertainty, where an indefinite number of possibilities are still open; a state which is indeterminate, not final; and a state in which the obtained results are yet far from being satisfactory, or in need of refinement. In a state of inconclusiveness, there is no *a priori* justification for terminating a process other than the fact that available resources and/or the motivation for pursuing the original objectives might have been exhausted, or directed to other objectives. A state of inconclusiveness will place a stress on the person, organization, or system that is experiencing it, and the response to the feelings of frustration, confusion, and indeterminacy associated to this state is critical in determining the lifetime track record of the involved actors.

In line with the above general discussion, the specific concept of *creative inconclusiveness* is defined as a state of uncertainty in a creative process. Creative inconclusiveness is not an accident: given the fact that the outcomes of a creative process are *a priori* unknown (otherwise they would not be creative), uncertainty permeates

most of the creative experience. A state of creative inconclusiveness can have intrinsic causes: the creative actor(s) might not: know how to precisely define the area of focus for the creative process; have sufficient motivation to invest in the creative process; have sufficient competence or information about the domain of knowledge that is relevant to the creative process; be able to generate creative ideas and produce outcomes; be able to extract the value of the produced outcomes; and have sufficient resources to bring the ideas to a tangible prototype or implementation. On the other hand, a state of creative inconclusiveness can have causes that are extrinsic, coming from the sociocultural environment within which the creative process is embedded: the proposal for a creative process might be rejected; the necessary resources for carrying out the process might be denied or insufficient; the creative process might be stifled by the extant culture or conceptual climate; the value of the creative products might be denied or insufficiently recognized by the gatekeepers; the creative products might be altogether rejected; the market might not be ready for the creative products; competing outcomes might be successful and thus obscure the value of the obtained results; and the resources necessary for the implementation of the creative products might be denied. Table 1 recaps several intrinsic and extrinsic causes for creative inconclusiveness. In general, the higher the level of ambition of a challenge, the higher the possibility to remain for long times in states of creative inconclusiveness. The ability to survive and emerge out of this state is a key requirement for creative achievement, as detailed below.

Creative Inconclusiveness in the Dynamic Creativity Framework

According to the standard definition of creativity as identified by Runco and Jaeger (2012), *creativity requires both originality and effectiveness*. In this form, the definition can apply to a product, a person, a process, or an environment. Originality is sometimes replaced by novelty (even though an original work is not only novel but also surprising

and authentic), while effectiveness is sometimes equivalently replaced by usefulness or appropriateness. Effectiveness is domain specific: it can refer to aesthetics in the arts, elegance, and power of explanation in science, performance in engineering, and so on. In this standard definition, the question of how originality and effectiveness are assessed is left implicit. This can be made more explicit by referring to the definition by Stein (1953, p. 311), who stated that “*The creative work is a novel work that is accepted as tenable or useful or satisfying by a group in some point in time.*” This definition, which is clearly oriented towards defining a creative product, clarifies the fact that the assessment of the originality, novelty, effectiveness, and usefulness is not an objective fact but rather a subjective process that depends on the actors involved at a certain time, in a specific sociocultural milieu. Both of these definitions are associated to a *static* framework for creativity studies, one that focuses primarily on instances of *creative achievement*, a state in which the creative actor(s) or the environment or both positively recognize the emergence of a creative outcome. Indeed, the standard definition of creativity, and all those definitions that similarly concentrate on the definition of a state of success, only covers the instances of creative achievement, and leaves out inconclusiveness as if this state were not worthy of being considered “creative.” In particular, if and when the outcomes of a creative process are rejected by society, under the static framework the creative process would *fail*. This is an important problem as it creates a gap in the theoretical framework: indeed, most of the reality of the creative process occurs actually within the boundaries of creative inconclusiveness.

Vice versa, when a *dynamic* theoretical framework is adopted for creativity studies, creative inconclusiveness becomes an essential concept, indeed a cornerstone. The dynamic creativity framework descends in turn from the dynamic definition of creativity (Corazza 2016) which foresees that *creativity requires a potential for originality and effectiveness*. The key difference resides in a single word: potential. The potential of a creative actor, process, or environment might be

Creative Inconclusiveness, Table 1 Intrinsic and extrinsic sources of creative inconclusiveness

Creative inconclusiveness	
Intrinsic causes	Extrinsic causes
Creative actor(s) has: • Insufficient focus • Insufficient motivation • Insufficient information • Difficulty in generating ideas • Difficulty in seeing the value of ideas • Insufficient resources for idea prototyping or implementation	Embedding environment: • Rejects proposal for creative process • Denies necessary resources to carry out project or to implement outcomes • Depresses motivation of actors • Stifles creative culture or climate • Denies value of creative products • Values more competing products

latent. When the potential associated to the outcomes of a process is recognized, an instance of creative achievement occurs. On the other hand, when any of the elements listed in Table 1 impede the recognition of the potential for originality and effectiveness, then a state of creative inconclusiveness is instantiated in the course of a creative process, even if the potential for originality and effectiveness is extremely high. The concept of potential allows the possibility for the same product to be considered very creative, moderately creative, or noncreative by different people, in different times or cultures. For this reason, in the dynamic creativity framework the word “assessment” is often substituted by “estimation.” Given that the distinction between achievement and inconclusiveness will never be so sharp as a black or white dichotomy, the dynamic definition of creativity is able to cover the entire scale of grey nuances between the extreme cases of total failure and eminent creative success, corresponding to very low (or theoretical zero) to very high (or a theoretical maximum) originality and effectiveness, and knowing that any judgment can change over time and culture. In other words, within the dynamic theoretical framework the *entire* process is considered to be creative, as long as it challenges the state of the art in order to have a potential for originality and effectiveness,

and this allows to consider creative inconclusiveness as pertaining properly to the realm of creativity studies. What characterizes core creativity in an epistemological sense is the fact of going beyond the boundaries of existing knowledge, exploring untested possibilities, irrespective of the fact that in doing so one might or might not be awarded a creative achievement. Given the fact that the state of creative inconclusiveness corresponds to uncertainty, open alternatives, indetermination, unfinished processes, and unexplored possibilities, it should be clear that the adoption of the dynamic creativity framework is essential in order for the creativity construct to be part of an encyclopedia of the possible.

Challenging the state of the art and exploring new possibilities is not only a prerogative of the human species. All other forms of life in flora and fauna evolve, and the entire universe evolves and expands. The search for new possibilities can therefore be seen at cosmological level. All of these phenomena can be seen in a unifying theoretical framework identified as the dynamic universal creativity process (DUCP), introduced in Corazza (2019), defined as the active ensemble of all creativity episodes in the history of our cosmos. Different layers of complexity at the material layer, biological layer, and socio-psychological layer can be shown to be interconnected through creativity episodes, the consequences of which extend indefinitely into the future. Indeed, creativity episodes can never be considered to be terminated in any hard sense, even in the presence of some form of creative achievement. For any given creativity episode, it is always possible to indefinitely continue a process of refinement of creative outcomes, irrespective of the response one receives from the environment. For any given product, the process of dynamic creativity estimation has no predetermined end, and by recognizing today a new form of value for an episode that occurred in the past, we effectively have an impact on the past itself. In other words, the creative process represented by the DUCP transcends the specific actors and extends indefinitely over time: inconclusiveness opens all possibilities for further exploration.

Creative Inconclusiveness: A Curse or a Blessing?

After the short DUCP digression presented above, we return here to the socio-psychological perspective, focusing on the modern era of the human society. It should be evident that it is natural for humans to expect some form of creative achievement out of their efforts. The minimum level is that of personal satisfaction in a process of personal growth, a situation that Kaufman and Beghetto (2009) identify as a form of mini-c creative achievement. However, when one is striving for higher forms of recognition at professional or eminent level (Pro-C and Big-C creativity in the terminology of Kaufman and Beghetto 2009), personal satisfaction becomes insufficient and might leave room to frustration when any of the extrinsic causes for creative inconclusiveness listed in Table 1 occur.

The fundamental question is whether an extant state of creative inconclusiveness brings only negative consequences, or if it can be considered to be potentially beneficial in the longer term. The answer to this question depends fundamentally to personal characteristics of the actor(s) involved in the creative process. In a study by Agnoli et al. (2019), an experiment was conducted in order to measure the effects of a manipulation on the feedback offered to the participants in response to their declination of alternative uses of common objects, in a classic alternative uses test (AUT; Guilford 1967). While the participants to this experiment were told that the computer had the ability to interpret natural language in real time and measure the creativity of the responses by exploiting a vast archive, in reality the system was repeatedly producing two predetermined manipulations: in the negative feedback condition, participants constantly received the same feedback: "The creativity of your responses is low" and in the positive feedback condition, participants constantly received the following feedback: "The creativity of your responses is high." The emotional intelligence trait (Trait EI) of the participants was measured through the TEIQue-SF scale (Petrides 2009), in order to have information on their ability to manage their emotional response. Finally, the

originality of the responses given by the participants was measured a posteriori by external judges. The results of this experiment are revealing. Under the negative feedback condition, which is clearly a proxy of the extrinsic causes of creative inconclusiveness, the low-trait EI participants showed a decrease in their creative performance, exposing a tendency to “give up.” On the other hand, in the same artificial condition of creative inconclusiveness, high-trait EI participants showed a progressive increase of originality of their responses. In other words, they were able to turn the negative energy of the frustration they were experiencing into a positive force for the production of more and more creative outcomes (Agnoli et al. 2019). This persistence and ability to turn the negative experiences of creative inconclusiveness into an incentive for further investment is a key characteristic of essentially all of the great minds that we consider as geniuses. A few eminent examples are reported in the next section.

Eminent Cases of Creative Inconclusiveness

The following examples of Thomas Alva Edison, Guglielmo Marconi, Steve Jobs, Jean-Baptiste Lamarck, Vincent Van Gogh, and Leonardo da Vinci are eminent because of their acclaimed creative achievements as geniuses; but an inner analysis of their biographies reveals that they were also champions of living through prolonged conditions of creative inconclusiveness. So much so that, at least in the cases of Van Gogh and Lamarck, creative achievement was only posthumous.

Thomas Alva Edison is certainly one of the greatest inventors of all times, who in the course of his lifetime was awarded thousands of patents. Edison, living the exciting epoch of the rise of electricity and electromagnetism at the turn of the twentieth century, was exceptional in his vision of possible applications of these physical phenomena. Edison did not work alone, he led a team of engineers and technicians whom he drove through a very intense program of try and error, building

and testing large numbers of alternative solutions. Clearly, most of the tried alternatives did not lead to successful outcomes, and thus generated waves of frustration in Edison’s team, but his leadership was masterfully expressed in his ability to picture these moments as useful instances of creative inconclusiveness (Wills 2007, p. 383): *“I never allow myself to become discouraged under any circumstances. I recall that after we had conducted thousands of experiments on a certain project without solving the problem, one of my associates [...] expressed discouragement and disgust over our having failed ‘to find out anything’. I cheerily assured him that we had learned something. For we had learned for a certainty that the thing couldn’t be done that way, and that we would have to try some other way. We sometimes learn a lot from our failures if we have put into the effort the best thought and work we are capable of.”* Edison’s lesson is very clear: the information that can be gathered in a state of creative inconclusiveness has fundamental value when one is exploring virgin grounds; it serves as a guiding light, without which it is very unlikely that anything useful can be found.

Around the same epoch, Guglielmo Marconi was working on his invention of wireless telegraphy, the development of which was a continuous refinement and development of the initial idea in a quest to reach longer and longer connection distances. In this sense, Marconi’s example is paradigmatic to show the indefinite duration of a creativity episode: refinement can continue indefinitely, irrespective of the fact that one has already obtained some (large or small) creative achievements, as long as one has the resources and the willingness to continue to pursue one’s objectives. In 1901, Marconi set out to perform his boldest experiment ever: the crossing of the Atlantic Ocean, from Cornwall in England to Newfoundland in Canada. Extrinsic causes of creative inconclusiveness worked very strongly against this idea: the physicists of the epoch, not knowing about the existence of the ionosphere (which of course Marconi was not aware of, as well), proved mathematically that this experiment was impossible. Marconi, 27 years old at the time, resisted all this negative criticism and overcame the harsh

environmental difficulties (the first transmission was received in Canada on December 12, 1901), before he could declare success. But this was not enough: the outside world still did not believe him, the press implied a fraud: Marconi's answer was to start a commercial service for transatlantic communications, definitely proving the truth of his creative achievement.

Taking an example from modern times, Steve Jobs is certainly remembered as one of the most impactful innovators in the information society, with planetary successes such as the iPod, the iPhone, and the iPad. However, the list of products conceived by Jobs that failed on the market or never made it to the market is probably even longer. Citing a few examples: the Apple Lisa, Macintosh TV, the Apple III, and the Powermac g4 cube. It should be underlined that often times the principles contained in a product that failed was then utilized by Steve Jobs, in whole or in part, in another product that became a success. In other words, in order to really analyze and understand the overall creative career of Steve Jobs, and extract from it useful lessons for future entrepreneurs in the high-tech sector, it is necessary to consider not only his creative achievements but also, and perhaps more importantly, his states of creative inconclusiveness and how these led to success through a path of reinvention and risk-taking.

The botanist Jean-Baptiste Lamarck was one of the first to formulate a complete framework for biological evolution, which in his view was based on two fundamental laws. The first law of *use and disuse* foresaw that during the course of the development of an organism, a more frequent use of an organ tends to consolidate it and make it stronger, while its permanent disuse progressively weakens it, reducing its functional capacity possibly down to zero. Lamarck's second law of *inheritance of acquired characteristics* established that the modifications to living organisms in terms of acquisition and losses of functionalities and characteristics as determined by the first law can be inherited, provided that they are common to both sexes. Lamarck's theories soon fell into a disgraceful state of creative inconclusiveness due to the contemporaneous rise of the Darwin's theory

on the *Origin of Species* (1859), establishing that inheritance is fundamentally based on genetics and not on the influence of the experience. For more than a century, this seemed to be the end for Lamarck's ideas. However, dynamic changes are presently happening in the study of the biological layer of the DUCP, and new findings in epigenetics today point to the fact that it is an actual possibility that Lamarck's theories could be at least partially correct (Wang et al. 2017): indeed, even though experience cannot modify one's DNA, it can modify the phylogenetic expression of DNA, in ways that can be memorized and transferred across generations. Creative achievement is therefore finally starting to dawn on Lamarck, after a long-time lingering in inconclusiveness.

Turning our attention to the world of the arts, there is general agreement about the fact that Vincent Van Gogh's production is one of the most creative of all times, joining a unique mastery of color, brushing technique, and imagination. Van Gogh started late as a painter, having tried other options in life which never led him to any form of happiness, but was then very prolific, producing hundreds and hundreds of works. Unfortunately, throughout all of his lifetime, he practically never met with creative achievement: he only sold a single painting in his life. He was probably the hardest critic of his own work, and his ability to obtain what would be posthumously considered to be marvelous technique only came through excruciating efforts, as, for example, he himself described in a letter to his brother Theo (Brower 1999, p. 686): "*I also worked on a large [figure] and have scraped it off twice, which you perhaps would have thought too rash if you had seen the effect; but it was not impatience, it was because I feel I can do better by grinding and trying, and I absolutely want to succeed in doing better, however much time, however much trouble it may cost.*" The success of Vincent Van Gogh was made possible only posthumously, also thanks to the determination of Johanna Bongers, wife of Theo Van Gogh, who published their letters and organized expositions of Vincent's paintings. She was fiercely criticized for this, but was able to persist and finally ensure perennial creative achievement for the artist.

Finally, let's consider Leonardo da Vinci, arguably the greatest creative mind of all times, who in the course of his lifetime generated ideas in more than 20 different disciplines, spanning the domains of the arts, science, and engineering. Leonardo's list of addressed disciplines includes painting, drawing, sculpture, anatomy, optometry, optics, botany, geology, geometry, aerospace engineering, mechanical engineering, hydraulic engineering, robotics engineering, military engineering, civil engineering, architecture, and city planning. As a consequence, Leonardo spent the larger part of his life dealing with multiple works in parallel, addressing different issues and finding cross-disciplinary associations. Leonardo produced the most famous painting in the world ("La Gioconda"), the most famous fresco ("Il Cenacolo"), and the most famous drawing ("L'Uomo Vitruviano"); he opened up anatomy, botany, and other fields of science and produced literally hundreds of engineering inventions. It should not come as a surprise that many of his operas remained unfinished. In this sense, Leonardo can be considered to have been not only the greatest creative achiever but also the greatest master of creative inconclusiveness.

Let's see some significant examples: when living in Florence, in the early part of his career, Leonardo was commissioned the "Battaglia di Anghiari" fresco for the Sala dei Cinquecento inside Palazzo Vecchio. Stifled by some technical difficulties, Leonardo did not finish the work in time, and for this reason he was not selected to be part of the florentinian delegation to the Vatican, and missed his chance to paint the Sistine Chapel. Out of this frustration, Leonardo decided to move to Milan and work at the service of Ludovico Sforza. There he designed and planned a gigantic equestrian statue for Ludovico's father, Francesco Sforza, which never saw the light because the necessary quantity of bronze was diverted from this project and used to produce cannons against the French invaders. In Milan he experimented with new fresco techniques for "Il Cenacolo" with a slower fix, which allowed him to work in parallel on several other projects, but these were revealed to be inferior to existing alternatives. A very long list of Leonardo's inventions remained

on paper at his time, and only saw the light several hundreds of years later. A few examples: the tank, the helicopter, the scuba diving equipment, and the contact lenses. In summary, Leonardo has been an unrivaled polymath whose mind was centuries in advance of his contemporaries, who really did not have the necessary knowledge in order to appreciate his production in all its value. Leonardo must have lived throughout his life in the frustration of creative inconclusiveness, unable to find anyone who could really estimate the extremely high potential for originality and effectiveness of his ideas, but this fact did not stop him or reduce his motivation at all.

Creative Inconclusiveness: Possibilities for Research

It would be a curious form of paradox to state that knowledge about creative inconclusiveness is concluded with this entry. In fact, given that most of the attention in creativity studies has traditionally been devoted to creative achievement, much remains to be explored in terms of the phenomena that characterize states of creative inconclusiveness in individuals, in groups, in organizations, and in societies. At the level of the individual engaged in a creative process, creative inconclusiveness should be studied in relation to its neural correlates, cognitive components, and emotional and motivational components. In groups, elements of positive teamwork and leadership should be studied in correspondence to the dire straits that characterize creative inconclusiveness. This holds as well for organizations, with the very important case of companies, both of large and small size. Finally, social and sociocultural environments differ greatly in terms of the climate that they create around the instances of creative inconclusiveness. A hypothesis worth exploring is that creativity and innovation flourish in those sociocultural milieus that afford risk-taking, in appreciation of the benefits of learning the lessons that creative inconclusiveness can teach and of the avenues that it opens towards the unexplored possible.

Creative Learning

Ronald A. Beghetto

Mary Lou Fulton Teachers College, Arizona State University, Tempe, Arizona, USA

Abstract

Creative learning serves as a vehicle for the possible. Creative learning moves people from what is currently known to new ways of thinking and acting. More specifically, creative

learning refers to a process that results in new and personally meaningful understandings for oneself and others. The purpose of this entry is to provide an overview of the theoretical concept of creative learning and its posited relationship to the possible. Research and theoretical implications are also discussed.

Keywords

Creativity · Learning · Education · Creative learning · New possibilities · Creative contributions

Definition and History

Researchers have conceptualized creative learning in a variety of ways (see Beghetto 2016). Some have focused on the creative aspects inherent in learning (Guilford 1950; Sawyer 2012). Others have emphasized the learning that results in creative outcomes (Wyse and Spendlove 2007). Still others have taken a more encompassing focus, which has outlined the conditions, contexts, curricula, and factors that might be classified under the heading of creative learning (Sefton-Green et al. 2011).

Although there are differences in the emphasis of these conceptualizations, the concept represents a synthesis of creativity and learning. Creativity typically refers to that which has been judged as original and useful in a particular sociocultural and historical context (Plucker et al. 2004; Runco and Jaeger 2012). Learning typically refers to a process that results in a relatively stable change in a person or persons (Alexander et al. 2009). Creative learning has been defined as a “combination of intrapsychological and interpsychological processes that result in new and personally meaningful understandings for oneself and others” (Beghetto 2016).

When considering these definitions together, the overlap between creative learning and the two concepts it emerged from is quite clear. Moreover, the connection to the possible is also suggested in this definition, because creative learning results in the possibility of new and meaningful understandings. Creative learning, however, differs from broader conceptions of creativity and learning in several important ways. Specifically, creative learning

Creative Learning, Fig. 1 Core components of creative learning

represents a special case of creativity, which is constrained by an educational focus. Researchers interested in the concept of creative learning are concerned with the genesis of new understanding in the context of educational settings broadly defined. Moreover, creative learning also focuses on the creative contributions to one's own and others' understandings, which emerge from the combination of new learning stimuli and existing knowledge and experiences. In this way, creative learning represents a more epistemologically and educationally focused aspect of the broader concept of creativity.

Creative learning also represents a special case of learning. Creative learning is concerned with the personal and sociocultural processes that result in creative contributions to one's own understanding and the understanding of others. This emphasis goes beyond reinforcing, matching, or reproducing existing understandings and toward the development of new and possible

understandings (Beghetto and Schuh [in press](#)). These new and possible understandings can be reflected in ideational, behavioral, or material artifacts and can be judged to be creative contributions by oneself or others.¹ In this way, creative learning focuses on the combinatorial and emergent aspects of learning, which represent key characteristics of creativity (Sawyer [2012](#)). Figure 1 highlights the key features of creative learning (based on a previously introduced model of creative learning, see Beghetto [2016](#)).

¹I want to thank the editor of the encyclopedia for requesting clarification on whether creative learning is limited to mini-c creativity. It is important to stress that although creative learning may often be experienced at a more subjective and ideational level (e.g., mini-c creativity, Beghetto and Kaufman [2007](#)), it is also possible that the outcomes of creative learning can be represented in behavioral and material artifacts, which can be recognized by others as creative contributions (e.g., little-c or larger-c creativity, Kaufman and Beghetto [2009](#)).

The model of creative learning depicted in Fig. 1 posits that the process starts with an encounter with a learning stimulus, which serves as a *new possibility* for engaging in creative sense-making. This encounter can prompt a *creative combination* between the new possibility and existing understanding that, in turn, results in a *creative contribution* in the form of a new understanding. The model also posits that these core components can simultaneously operate in and between people in educational settings. As will be discussed in the following sections, although the same components are at play in and between people, they take-on different features at the intrapsychological and interpsychological level. Prior to discussing how these components play out differently at each level, it is important to highlight a few core assumptions illustrated in Fig. 1.

First, is the recognition that although there is a sequence or process for how these components operate (from left to right), the model is recursive. Similar to other models of creative thinking (Runco 2018), the recursive aspect of this creative learning model occurs both in the potential movement back and forth between components as well as iterative cycles throughout the model. Moreover, the intrapsychological (individual) and interpsychological (social) spheres represent permeable boundaries that are always and already interconnected and mutually influencing as denoted by dotted lines. Specifically, the sociocultural context continually influences students' learning trajectories and idiosyncratic understanding of academic subject matter (Schuh 2017). Similarly, individual students also impact and give shape to their sociocultural context; this can be seen in cases where students' unique perspectives are encouraged and considered by teachers and peers (Beghetto and Schuh *in press*; Gajda et al. 2017).

The permeable and embedded boundaries drawn between the individual and social in Fig. 1 highlight how the same components can operate differently at each level, while still recognizing that the individual is always influenced by the sociocultural and the sociocultural is always influenced by the individual.² Moreover, as is the case with how other creative processes have

been conceptualized, the creative learning model depicted in Fig. 1 acknowledges that the entire process is also influenced by sociohistorical and broader contextual factors (Glăveanu 2015).

Finally, the components and processes represent theoretical assertions, not prescriptions. Researchers can draw on these assertions to design studies aimed at empirically testing the posited processes represented in the model. The following sections briefly outline the key assertions associated with the core elements of creative learning at the intrapsychological (personal) and Interpsychological (sociocultural) level. The entry closes with a brief discussion of how the model connects to the possible and directions for research.

Components of Creative Learning

Intrapsychological Sphere

The interpsychological sphere of creative learning posits that personally meaningful understanding results from an encounter with a new learning stimulus, which is then meaningfully combined with one's existing understanding. Specifically, in the context of formal education, students are introduced to academic subject matter, which serves as a potential stimulus for creative learning. Learning stimuli can come in many forms, such as ideas, concepts, images, materials, and experiences. Regardless of the form that learning stimuli take, they represent a new possibility for transforming one's existing knowledge and experiences into a new and personally meaningful understanding (Beghetto and Schuh *in press*).

The model posits that students must find the learning stimulus optimally novel to catch their attention (Beghetto 2016), otherwise it may be dismissed as already known (not sufficiently

²It can be argued from a sociocultural perspective that the socio-cultural does not simply influence individuals from the "outside," but rather that the socio-cultural is interdependent with and co-constitutive of the creative learning process. I want to again thank the editor of the encyclopedia for noting this important sociocultural distinction.

novel) or too discrepant (overly novel). This determination is based on a student's prior learning trajectory, which includes student's prior knowledge and idiosyncratic experiences (Schuh 2017).

If a learning stimulus is sufficiently novel, then this new possibility is considered in light of what the student already knows. Put simply, this process refers to a combinatorial, sensemaking process that can result in a new, emergent understanding resulting from the combination of what *is* known with the newly encountered possibility. This generative and combinatorial process aligns with what researchers have long recognized as central to creative endeavors (Rothenberg 2015; Ward and Kolomyts 2010).

More specifically, it involves engaging the creative imagination to envision new insights, which can move students beyond their existing understandings and toward new learning (Beghetto and Schuh *in press*; Vygotsky 2004). Doing so opens up a broad horizon of possible understandings. Although the potential understandings that can be generated from this process are constrained by a student's prior learning trajectory, the resulting understanding (like all creative outcomes) is difficult to predict at the outset due to its emergent and dynamic nature (Sawyer 2012).

Consequently, there are various possible outcomes of this individual combinatorial process. In some cases, students may not be able to reconcile a newly encountered learning stimulus with what they already know. In such cases, they may choose to ignore the new possibility or seek out assistance. In other cases, the combinatorial process may result in the reinforcement of what is already known, rather than the development of a new understanding. This type of reinforcement or Piagetian assimilation of information is a common process of academic learning (Von Glasersfeld 2013) but does not represent a case of creative learning.

In order for creative learning to occur at the individual levels, student's need to be able to generate a new and personally meaningful understanding, which represents a blend of the learning stimulus with their existing understanding. In this way, their prior understanding has been transformed by the new experience or information

they have encountered. Learning theorists describe a similar transformation in various ways, such as accommodation (Von Glasersfeld 2013) or conceptual change (Zaitchik et al. 2016). In the context of creative learning, the emergent understanding represents a creative contribution to the individuals understanding. What creativity researchers have called subjective, personal, or mini-c creativity (Beghetto and Kaufman 2007).

The model of creative learning further posits that the personal mini-c understanding can transition into a little-c (classroom-level) creative contribution to the learning of others. As will be discussed in the next section, the model of creative learning represents a way of conceptualizing how personal creative insights can convert into social creative contributions. Prior to discussing how these asserted components and processes play out at the social (interpsychological) level, it is important to briefly mention the recursive possibilities that can occur throughout the process.

Specifically, creative contributions and creative combinations can spark additional combinations, possibilities, and contributions. The components and processes are not simply additive sequences. Although it is possible that a new learning stimulus will result in a new insight, it is also possible that a learning stimulus can provoke multiple creative combinations and thereby generate multiple creative contributions to one's understanding.

Moreover, as will be discussed in the next section, a student's new understanding can serve as a stimulus for the learning of others. In this way, the meaning-making process of creative learning can be thought of as representing a form of unlimited semiosis (Eco 1986). Specifically, unlimited semiosis in this context refers to the potentially endless process of new understandings serving as new stimuli, which can provoke new creative combinations and, in turn, creative contributions to one's understanding and the understanding of others (Beghetto and Schuh *in press*).

Interpsychological Sphere

The components of creative learning operating in the interpsychological sphere are conceptualized

as the potential for students' unique insights to contribute to the learning of others (Beghetto 2016). More specifically, the model posits that when students have an opportunity to share their new and personally meaningful understanding with others a window of the possible opens, which has the potential to contribute to the understanding of everyone involved. The greater the diversity within classroom contexts and the greater the difference in perspectives of the individuals who inhabit those contexts, the greater the potential for creative learning to occur for the students and teachers in those settings (Glăveanu and Beghetto 2016).

Specifically, the student who shares a new and personally meaningful understanding will have an opportunity to receive feedback that can help clarify, correct, or verify that understanding. This is particularly important in an academic context wherein there are existing norms and conventions for determining whether an understanding is accurate or at least compatible with what is known. Consequently, such feedback opportunities are typically viewed as a necessary aspect of formal learning (Lipnevich and Smith 2018), including creative learning.

Students who share their understanding also have an opportunity to make a creative contribution to the understanding of their peers and teachers. In this way, a student's new understanding can serve as a learning stimulus and new possibility for how others understand the subject matter under consideration. As discussed, the transfer from individually creative to socially creative can also be viewed as the transition from mini-c to little-c creativity (Beghetto and Kaufman 2007). This transition is also similar to what has elsewhere been described as the movement from primary to secondary creativity (Runco and Beghetto 2019). Primary creativity refers to the creator producing a creative outcome after engaging with some new medium or subject matter. Primary creativity can transform into secondary creativity when an external audience engages with the primary creative outcome and recognizes it as creative. Importantly, even when individuals are engaged in primary creativity they are still engaging in dialogue with "internal audiences" of past, present, and future interlocutors (Beghetto 2017;

Glăveanu 2017), which can influence how the primary creative outcomes take shape. Secondary creativity thereby refers to the creative experience of external audiences who engage with creative artifacts resulting from primary creativity.

Specifically, when students share an unexpected or different conception (primary creativity) and teachers and peers are willing to engage with that conception and try to make sense of it in light of their own existing understanding (secondary creativity), it is possible that the combination will result in a creative contribution in the form of a new understanding for others. In this way, the core components that result in a creative outcome at the individual level reoccur at the sociocultural level. As mentioned, given the recursive possibilities involved in creative learning, a creative contribution made by students to their peers and teachers can, in turn, result in the generation of additional possibilities that serve as new learning stimuli for others.

There are various individual and sociocultural factors that influence whether students will share their new perspectives and for those perspectives to make a creative contribution to others, including students' creative confidence (Karwowski et al. 2019), willingness on the part of teachers and students to take the risks necessary for exploring different perspectives (Glăveanu and Beghetto 2016), students perceiving the learning environment as supportive (Anderson et al. 2017), and teachers and students willingness to break from the prototypical and more convergent patterns of interaction in the classroom (Cazden 2001).

Taken together, the core components of creative learning (i.e., new possibility, creative combination, and creative contribution) represent a special case of both creativity and learning. As will be discussed in the following section, the posited processes involved in creative learning at both the individual and sociocultural level also represent various forms of the possible.

Creative Learning and the Possible

The possible is always and already present within each component and phase of creative learning. Indeed, as illustrated in Fig. 1, a

learning stimulus is itself a new possibility. The uncertainty entailed in the possible, but not yet known outcome, of engaging with a learning stimulus motivates people to resolve the doubt they are experiencing (Beghetto and Schreiber 2017). The resolution of uncertainty can occur in at least one of three ways: accepted, ignored, or combined. First, a stimulus that appears novel may be accepted as a case of what is already known. A novel stimulus may be too discrepant to be understood and is thereby dismissed as incomprehensible. Finally, a learning stimulus may be perceived as sufficiently novel to capture a person's attention and thereby move a person or group into a new state of the possible, which involves an effort to make sense of the stimulus in relation to what is already known.

The possible becomes further animated in the combinatorial phase because of the uncertainty involved in the outcomes that can be generated from this sense-making process. This, in turn, can result in the possibility of developing a new and personally meaningful understanding, which can lead to further possibilities for creative outcomes when shared with others. Moreover, the recursive nature of the process continues to keep the possible at play during each phase of creative learning.

In sum, the possible is shot through the creative learning process. Indeed, the possible remains active even once uncertainty is seemingly resolved in the form of a new understanding. Given that a person's understanding continues to develop and change over time, the potential for new creative contributions to one's own and others learning remains ever present. In this way, the outcomes of creative learning remain "inconclusive" (Corazza 2016) and filled with potential for change. As a result, creative learning can be thought of as playing a central role in clarifying and actualizing a broad spectrum of possibilities; including *possible pasts* (e.g., ways in which we reflect upon and build on our prior understandings), *possible futures* (e.g., new openings, alternatives and directions our understandings can take), *possible selves* (e.g., new ways of understanding ourselves and others), and *possible worlds* (e.g., new understandings about what our world is and can be) – see Glăveanu ("The

Possible as a Field of Inquiry," this volume) for a broader discussion of these different areas of possibility.

Directions for Theory and Research

The concept of creative learning discussed herein offers creativity researchers a lens for considering the role of the possible in the context of formal learning environments. The three components outlined in Fig. 1 provide a framework for researchers to examine how learning stimuli might serve as a prompt for generating new possibilities and ultimately contribute to the learning of individual students, groups of students, and teachers.

Theoretical and empirical work, aligned with this conception of creative learning, has been growing in recent years (Anderson et al. 2019; Gajda et al. 2017; Jankowska et al. 2018; Karwowski 2018). Such work has helped to refine and expand on the theoretical assertions of the model, including highlighting the importance of researchers developing and employing different methodological approaches to examine the multifaceted features of creative learning.

More specifically, this line of research has demonstrated how researchers can use blended designs to examine more fine grained, dynamic, and micro-longitudinal features of creative learning in classroom settings (Gajda et al. 2017); illuminate the inward and outward features of creative learning (Anderson et al. 2019); and tease out potentially different cognitive processes at play in creative learning as well as different ways students represent their understanding of academic concepts (Jankowska et al. 2018).

Although this work is promising, much additional work along these lines is needed. Studies are needed to further examine and test out the assertions posited in this model of creative learning. In particular, additional research is needed to simultaneously examine the individual and sociocultural aspects of creative learning and identify the factors and subprocesses at play in moving from creative learning stimuli to creative contributions in the form of new understandings.

Future work might therefore explore questions, such as:

- *What other mechanisms, components, and mediating or moderating factors are missing or misspecified in current conceptualizations of creative learning?*
- *What are the most promising methods and analytic techniques for identifying and testing the posited components of creative learning and what kinds of insights might be derived from such research with respect to clarifying the individual and socio-cultural factors involved in creative learning?*
- *How might clarifying the nature of creative learning and its relationship to the possible build on and inform related lines of theory and research in the fields of creativity studies and the learning sciences?*

With advances in more sensitive and dynamic methods and analytic techniques (Beghetto and Corazza 2019), including the growing work occurring both in neuroscience (Jung and Vartanian 2018) and sociocultural perspectives on creativity (Glăveanu et al. 2019), researchers are in a position to move theory and research forward on the concept of creative learning. Such work can help greatly in clarifying the nature and consequences of creative learning, including clarifying the role the possible plays throughout the process.

Creative Mindsets

Maciej Karwowski

Institute of Psychology, University of Wrocław,
Wrocław, Poland

Abstract

What makes creativity *possible*? Here, I posit that to make creativity *possible*, people must believe that a set of skills usually described under the umbrella of creativity is changeable and open to growth. Yet, many individuals tend to believe that creativity requires exceptional talent and that this talent is inborn and fixed. I discuss the concept of creative mindsets: subsets of implicit theories of creativity that refer to perceived creative potential sources. Creative mindsets' structure, nature, and antecedents are overviewed, and future research areas are proposed. It is concluded that mindsets form a particular case of *impossible-versus-possible* and *impossible-and-possible* distinctions, as they specifically refer to a *possibility* and *impossibility* to change, learn, and develop creativity.

Keywords

Creative mindsets · Fixed mindset · Growth mindset · (Im)Possibility of creativity

Is it *possible* to create something if individuals do not believe in their potential to propose something new and meaningful (see ► **“Creativity”**)? Although apparently straightforward, in fact, this is by no means a trivial question. On the one hand, sometimes people solve problems quickly: They have flashes of insight (see ► **“Insight”**) that had not been anticipated and result in great discoveries. On the other hand, when anecdotes are ignored, it becomes clear that such situations are

scarce. Creative activity is a long-term one, and it requires a lot of effort and persistence. To deal with creative tasks effectively, people must possess certain skills relevant to the domain and be able to self-motivate themselves to overcome obstacles they meet during the creative process (see ► [“Self-Regulation”](#)). The argument this chapter is built on states that one of the very basic, yet necessary, conditions to create is having a particular perception of creativity – the so-called creative mindset. More specifically, based on the recently proposed (Karwowski and Beghetto 2019) and elaborated elsewhere (Karwowski et al. 2019a) theoretical model of creative behavior as agentic action (CBAA), I posit that creative mindsets play an essential role in the complex relationship between creative potential, creative confidence, valuing creativity, and creative behavior.

This chapter consists of three main parts. After providing a brief definition of creative mindsets, its history is discussed by first reviewing crucial works on mindsets in general and then citing specific research that deals with creative mindsets. Then, the CBAA model is introduced and the hypothesized role of mindsets in this model is emphasized. Promising areas for future studies and still open questions that should be answered by consecutive investigations conclude this chapter.

From Mindsets to Creative Mindsets

Creative mindsets refer to people’s implicit theories about perceived sources of creativity. They are implicit as people are not always consciously aware of them; quite the opposite: They could have and often do have problems verbalizing them. These theories are also naïve, as they do not necessarily go hand in hand with professional knowledge of creativity scholars and findings obtained in empirical studies. Often, these theories are at odds with research results.

Some people believe that creative skills are fixed. When defining creativity, they usually refer to “Big-C” level accomplishments and attribute creativity to a small group of geniuses (fixed

mindset). Others define creativity as *possible* to be developed; they see it as a set of trainable skills that could be enriched at home, in school, and at work (growth mindset). Interestingly, things can also go the other way: When people are asked to think about great creators (e.g., Albert Einstein or Marie Skłodowska-Curie), they tend to think about creativity in a more fixed way, while when primed with everyday creativity, their growth mindset grows (Karwowski et al. 2020). Importantly and intriguingly, people can integrate fixed and growth theories when they think about creativity. A growth mindset defines what is *possible* – it focuses on the *possibility* to change and develop. A fixed mindset is instead focused on *impossibility* as it postulates stagnation. Thus, mindsets’ integration means that people do not think about creativity in terms of *impossible versus possible*, but rather *impossible and possible* at the same time. This paradox requires some unpacking. First, however, let us clarify the main concepts and their theoretical traditions.

The concept of mindsets emerged from early studies on implicit theories of intelligence initiated by Dweck (Dweck et al. 1995). This line of research has shown that while some people believe that intelligence and other abilities are innate, fixed, and difficult to change (later called fixed mindset), others see human skills as malleable, or *possible* to be developed through effort, instruction, and practice (so-called growth mindset). Several studies, including preregistered interventions, demonstrated that mindsets are related to students’ academic motivation and engagement: their resilience (Yeager and Dweck 2012), persistence (Mueller and Dweck 1998), and perceived self-worth (Dweck and Leggett 1988). One of the crucial theoretical predictions of early works was that a fixed mindset serves as an antecedent of the so-called performance goals (Karwowski and Anderson 2021), while growth mindsets build learning goals. In other words, people who hold a fixed mindset are driven by the focus to avoid mistakes. As they attribute outcomes to innate abilities, they feel frustrated and helpless when faced with setbacks and often achieve less at school or at work. At the same time, individuals who hold growth mindsets

adopt learning-oriented goals, attribute performance to the effort, and prefer challenging tasks that are not void of errors, but allow them to improve their skills and achieve more.

Creative Mindsets: Complexities and Paradoxes

Creativity is everywhere, at least potentially. The capacity to perceive reality in new ways, transform what is given, and produce ideas, behaviors, and works that make the world better is at the heart of humanity. Thus, it is not surprising that creativity or creativity-relevant characteristics, such as complex problem solving, are listed among the most critical skills for the new millennium (Ananiadou and Claro 2009). However, although the potential (see “► Potential”) to create is indeed among the very essential characteristics of every psychologically healthy individual, fulfilling it and choosing a creative way of living are far less common (see Karwowski and Wiśniewska 2021). Why is this the case? Why do some people decide to invest their time and effort to develop new ideas while others feel that such action makes no sense? Creative mindsets might be among the reasons.

Indeed, people's perception of themselves and the world around them matters for their motivation and activity. There are convincing empirical arguments that perceiving creativity as changeable or fixed influences people's activity (O'Connor et al. 2013). Suppose someone equates creativity exclusively with the activity of Nobel Prize winners. In that case, such a belief will naturally lead to a conviction that creativity is rare and impossible in ordinary people. Would such a person see any sense in engaging in creative activity and developing their skills? Unlikely.

Consequently, such *creative impossibility* will have negative consequences for leisure time or hobbies, their professional decisions, and functioning on a job market, which emphasize creativity-related skills. Mindsets may also matter when one is faced with failure while dealing with creative tasks. Previous works discovered that incremental theorists (those who hold the growth mindset) deal better with failure, as they tend to

perceive it as an opportunity to learn (Burnette et al. 2013). But if people are entity theorists, meaning they hold fixed beliefs, they instead consider failure as a threat and this risk of failure demotivates them to undertake the activity (Haimovitz et al. 2011). Thus, people holding growth mindsets are expected to engage more in creative tasks, while there are good reasons to believe that people with fixed mindsets will tend to avoid difficult problems.

Empirical evidence is in line with these predictions. Indeed, previous studies have shown that a fixed mindset is negatively correlated with creative confidence (Karwowski 2014), engagement in creative thinking (Pretz and Nelson 2017), and creative achievement (Puente-Diaz and Cavazos-Arroyo 2017). It also increases the likelihood that one will stop activity after a failure (Beghetto and Dilley 2016). What is more, a fixed mindset negatively predicts efficacy in solving insight tasks (Karwowski 2014) and the ability to propose many different ideas to open-ended problems (divergent thinking; O'Connor et al. 2013). A growth mindset has been positively linked to creative confidence and valuing creativity (Hass et al. 2016; Pretz and Nelson 2017), fluency and originality of thinking (O'Connor et al. 2013), effectiveness of creative problem solving (Karwowski 2014), as well as solving insight tasks and divergent thinking (Karwowski et al. 2019b). A growth creative mindset predicted more general positive affect for teachers during the early stage of the school closure in the COVID-19 pandemic (Anderson et al. 2021).

Logically, fixed and growth mindsets are opposites: If people believe that creativity could be developed, they should not assume it is carved in stone – and vice versa. Yet, interestingly, there is growing evidence that creativity might be described using both fixed and growth terms at the same time (Puente-Diaz and Cavazos-Arroyo 2017). A large psychometric study suggests that although there may be a general “either-or” tendency to describe creativity, people are still able to hold both mindsets (Karwowski et al. 2019b). Although apparently paradoxical, this perception has been explained by both the complexity of creativity and the differences in laypeople's

knowledge about it (Karwowski and Brzeski 2017). Knowledge about creativity and valuing it increases the likelihood of holding both mindsets. Also, awareness about current theorizing in creativity literature (e.g., Kaufman and Beghetto 2009) could make it easier to accept that some creativity forms are trainable (mini-c, little-c), while other may be more fixed or special talent based.

Creative Mindsets as Mechanisms

One of the recent conceptualizations of creativity, namely the creative behavior as agentic action (CBAA) model, proposes that creativity is a certain kind of action: an agentic action. In this model, creative behavior is thought of as a decision an individual is making (Karwowski and Beghetto 2019; Karwowski et al. 2019a). CBAA theorizes creative potential – be it divergent thinking, rich imagery, or curiosity – as a necessary yet not sufficient condition of creative behavior. Abilities matter. Yet, whether an individual will make an effort to invest them into the long-term activity is – by definition – uncertain (see ► “[Uncertainty](#)”) and depends on many other factors. The CBAA model specifically describes and empirically tests two such factors and possible mechanisms. The first is creative confidence. According to the CBAA model, people higher in creative potential also tend to hold higher creative confidence (see ► “[Creative Self-Efficacy](#)”), which drives them toward activity and problem-solving. Creative confidence mediates the links between potential and achievement: The more potential people have, the higher their confidence, thanks to previous successes and social feedback they obtained. The second hypothetical factor is valuing creativity. This characteristic describes whether individuals perceive creativity as something important for their self-perception. If creativity is not among the desired characteristics, even high potential will not result in observable activity and achievement. A recent study (Beghetto et al. 2020) found another factor that might strengthen the relationship between creative confidence and creative behavior (and

subsequently – creative achievement): a willingness to take adaptive risks. People who are risk-takers seem to be more effective in using their creative confidence to develop creative achievement. Other sets of characteristics that likely intervene in the link between potential and activity are creative metacognition (Anderson and Haney 2020) and creative self-regulation (Zielińska et al. 2020).

What is the role of creative mindsets here? Although empirical evidence is scarce so far, some theoretical presuppositions presented elsewhere (Karwowski et al. 2019) hypothesized quite a complex, twofold role of creative mindsets. First, mindsets may qualify the relations between creative potential and creative behavior, and namely serve as moderators of this relationship, with expected links between potential and behavior being stronger among incremental than entity theorists. But perhaps even more importantly, mindsets can also shape other creative confidence beliefs. Indeed, prior research has demonstrated a positive link between growth mindset and creative confidence (Anderson et al. 2021; Hass et al. 2016; Karwowski 2014), while the correlations between mindsets and potential or behavior (achievement) are usually weaker and less systematic (Hass et al. 2019). Consequently, mindsets are hypothesized to play a double role in the revised CBAA model to shape confidence beliefs and moderate potential-behavior links.

Discussion

Making creativity real, namely transforming each person’s potential into an observable activity that may eventually lead to achievement, requires acknowledgment that changes in creativity-related skills are *possible* at all. This is precisely the place where creative mindsets come to play. While the growth creative mindset focuses on creativity as a skill that might be developed through practice, effort, and practical strategies, the fixed mindset pictures creativity in terms of its innate, mainly inherited, roots and links creativity with Big-C endeavors.

Although common sense suggests that the growth mindset is adaptive and the fixed mindset destructive for creative activity, the reality is much more complex. People categorized as entity theorists (high-fixed and low-growth creative mindsets) or incremental theorists (high-growth and low-fixed mindsets) are not the only possible categories empirical studies observe. Approximately one-fourth of participants in many studies are classified as complexity theorists, meaning people who hold growth and fixed creative mindsets equally high. What stands behind this apparently paradoxical category? How does it happen that some people perceive creativity as *possible and impossible* to be developed simultaneously? A recent study (Anderson, Katz-Buonincontro, Boussetot, Mattson, Beard, Land, & Livie, under review) found that teachers held these contradictory beliefs simultaneously because they had never given the origins of creativity much thought. What is particularly important and promising, however, is that this study also found teachers-focused interventions to be able to significantly reduce fixed mindset (Anderson et al. [under review](#)).

One reason for thinking about creativity in terms of both mindsets may be associated with a deeper understanding of what creativity is and richer experience in creative activity. Someone who spontaneously disentangles personal insights and everyday problem solving from more professionalized or even eminent creative behaviors might fit well into this category. Accepting that creative thinking and problem solving are natural for many ordinary people will lead to a growth mindset. Simultaneously, while people can perceive themselves as creative in their day-to-day activities, they can feel unable to achieve professional level, outstanding accomplishments. This leads to a fixed mindset – perceiving some levels as unachievable to anyone, but the selected very few. Thus, integration of mindsets might stem from a more nuanced understanding of what creativity means and clarity about its different aspects.

Future studies will benefit from exploring this line of thought and examining the more direct

links between creative mindsets and possibility thinking (Glaveanu 2020). Given the growing interest in noncognitive factors observed in creativity and possibility literature, closer empirical examinations of the role of creative mindsets for the possible seem especially promising.

Creative Problem-Solving

Gerard J. Puccio, Barry Klarman and
Pamela A. Szalay

International Center for Studies in Creativity, The
State University of New York, Buffalo, NY, USA

Abstract

Life and work in the beginning of the twenty-first century has been described as volatile, uncertain, complex, and ambiguous. In this fast changing, innovation-driven environment, Creative Problem-Solving has been identified as a fundamental skill for success. In contrast to routine problem-solving, with straightforward and repeatable solution paths, today's problems are described as being complex and wicked. To generate the possibilities that can effectively address complex problems, individuals need to draw on the highest level of human thought – creativity. Creative Problem-Solving explicitly draws on, and promotes, effective creative thinking. The purpose of this entry is to describe and distinguish Creative Problem-

Solving from other forms of problems-solving. Moreover, as Creative Problem-Solving is a deliberate creativity methodology, this chapter also provides a description of the more specific thinking skills that are embodied by the higher-order skill of creative thinking and are explicitly called on in Creative Problem-Solving. Complex problems require complex thinking, and Creative Problem-Solving provides a structured process that allows individuals to more easily and efficiently deploy their creative thinking skills.

Contrasting Creative Problem-Solving with Problem-Solving in General

Webster's dictionary defines problem-solving as the process or act of finding a solution to a problem. While this definition provides a general description of problem-solving, it does not provide a nuanced understanding of the range of problems humans encounter in their personal and professional lives. Problems can be routine, complicated, or complex in nature. Routine problems have clear procedures and predictable outcomes (Stokes 2013). Complicated problems also have clear procedures and predictable outcomes but involve the simultaneous coordination of multiple routine problems or problems for which expertise is crucial for success. Complex problems are described as being ill-defined, novel, and ambiguous (Mumford et al. 2000). Escalating levels of thinking are necessary for humans to respond efficiently and effectively to routine, complicated, and complex problems. Broadly speaking, routine problems require accurate recall, complicated problems require critical thinking, and complex problems require creativity (Anderson and Krathwohl 2001). The purpose of this paper is to describe a problem-

solving approach and the various forms of thinking that are necessary to respond to problems that are most open to, indeed demand, new and valuable possibilities, in other words *creativity*.

A wide range of effective problem-solving processes have been developed to support individuals as they contend with routine, complicated, and complex problems. Most of these approaches are domain or industry specific. In contrast, a relatively smaller number of problem-solving processes have emerged from the field of creativity studies that are designed to be broadly applicable across domains and disciplines. In this entry, we examine one such methodology called *Creative Problem-Solving*, CPS for short (Osborn 1953; Puccio et al. 2011). As the name implies, CPS is a *creative* approach to problem-solving and therefore is focused on exploring what is possible, beyond what is known and demonstrable. This creative process methodology has been shaped by roughly 100 years of practice and is informed by insights derived from the field of creativity studies. CPS is designed to facilitate and actively engage creative thinking, which is the most complex form of cognition known to human beings, as such CPS serves as a meta-framework for an array of more specific cognitive and affective skills. Finally, CPS mirrors the level of complexity and flexibility inherent in the creative process, which means this problem-solving process is unique in its ability to both react to challenges and anticipate opportunities.

To fully appreciate the value of CPS, it is helpful to begin by examining key concepts related to basic problem-solving. Problems are created by situations that necessitate productive change. A problem space is how a problem is represented based on an initial situation, a goal state, and a search space. Problem-solving processes incorporate stages, strategies, tactics, methods, and techniques to navigate a problem space. The solution path is the series of steps that move the problem-solver from the “the initial state (the given situation/the given problem) to the goal state (the desired situation/the solution)” (Stokes 2013, p. 247).

In general, the solution path to a problem can take one of two forms, depending on whether the problem is algorithmic or heuristic. Algorithmic problems are usually routine, sometimes complicated, but rarely complex. They are considered close-ended because they have a limited range of known solution possibilities and sometimes have just a single correct solution. As a result, the solution path for algorithmic problems is known, well-established, often sequential and generally predictable. Thus, there is no need to search for new possibilities as existing routines provide clear solution paths (Stokes 2013); creative thinking is not required or necessary.

Alternatively, heuristic problems are open-ended with no single set path to a predetermined solution. In fact, the path is shaped through a series of choices and decisions made as the problem is being solved. Any new data, insights, or ideas that emerge during this process can be used to reassess the situation and influence the criteria for the next decision. This happens repeatedly until there is satisfactory resolution. Therefore, the pathway is as unpredictable as the eventual solution, which must be discovered or created (Puccio et al. 2011). CPS was specifically designed to address complex open-ended problems that require a heuristic approach to the formulation of a solution path.

Algorithmic and heuristic problems can be further categorized by considering how individuals approach such problems, which is either in a

reactive or proactive manner (see Fig. 1, Problem Scenarios). As indicated earlier, problems are created by situations that necessitate productive change. These situations can be thrust upon us, in which case we need to react to them. In other cases, problems might be anticipated or discovered and proactively approached. When reacting to a problem that can be solved by algorithmic methods, formulaic processes can be used (i.e., established processes that lead to objectively correct solutions). In other cases, we might anticipate a future problem, for which we know how to respond. In such cases maintenance procedures are carried out to avoid problems that are anticipated. If you do not fuel your car up, either you will run out of gas (internal combustion engine) or battery life (electric vehicle). Predicaments occur when heuristic methods are needed to resolve an unexpected problem related to an established goal or area of performance. In other words, some change has occurred, and the problem-solver is uncertain about how to return to previous levels of performance. Opportunities appear when the possible opens up by taking a proactive approach using heuristic methods to change the current situation or to pursue an entirely new goal or outcome. Predicaments and opportunities, as depicted in Fig. 1, represent complex problems and therefore require a heuristic approach. The CPS process is designed to assist problem-solvers deliberately engage their creative-thinking abilities in order to produce

Creative Problem-Solving, Fig. 1 Problem scenarios. (Source: Puccio et al. (2011). Reprinted with permission)

new possibilities that successfully address predicaments and opportunities (Puccio et al. 2011). See Puccio et al. (2011) or Puccio et al. (2012) for a more detailed description of Fig. 1.

Because CPS is designed to manage ambiguity (relevant information is unknown; the solution path used to solve the problem is unknown; and the form of the solution is unknown or poorly defined), those engaged in the CPS process often experience a palpable sense of wonder about the possible. Problem-solving methods for algorithmic problems lack this sense of wonder due to the presence of considerable clarity; the problem space, the solution path, and the solution's final form are quite predictable. There is no need to engage the imagination. We suggest that CPS distinguishes itself from other problem-solving processes by leveraging ambiguity, encouraging a sustained exploration of what *might* be possible and providing techniques for many alternatives to be considered before a decision is made. This allows ample room for the imagination to wonder and wander, even as steps are being made along the narrowing solution path.

In conclusion, CPS is a transformational sensemaking process that ultimately bridges the gap between a current problematic state and a desired future possible state. CPS can also be described as a chaotic complex adaptive process, one that utilizes cognitive and affective skills in order to facilitate wonder about novel, poorly defined problems and their possible solutions. As a result, when people are trained in CPS, they develop the crucial problem-solving skills of flexibility and adaptability. Indeed, among the various creativity training programs, CPS has been identified as one of the most effective (Scott et al. 2004). In a world that is increasingly defined by change and complexity, creative problem-solving is now widely recognized as a vital twenty-first century skill. Unfortunately, while a recent *Bloomberg Businessweek* report indicated that creative problem-solving is the fifth most important skill sought by employers, it is the second most difficult skill to find (Otani 2015). Training in CPS can bridge that gap.

Creative Problem-Solving: An Introduction and Overview

Humans are innate creative problem-solvers. Since early humans developed the first stone tools to crack open fruit and nuts more than 2 million years ago, the application of creative thinking to solve problems has been a distinct competitive advantage for our species (Puccio 2017). Originally used to solve problems related to survival, the tendency toward the use of creative problem-solving to see, and then create, new possibilities naturally expanded to a wider range of human endeavors. As Morriss-Kay (2010) observed, “without these survival-enhancing functional origins, it is unlikely that we would have the neural equipment to create art” (p. 174). To be sure, it has been the unique human ability to apply imagination to solve problems that has resulted in the creation of our technological, social, and aesthetic world.

Creative problem-solving, when denoted in all lower case, refers to humans' evolutionary predisposition to employ higher-order thinking skills, namely, creative thinking, to solve complex problems. The kinds of complex problems humans contend with are not limited to tangible domains, such as science and technology, but also include the kinds of intangible problems found in such fields as philosophy, psychology, justice, and numerous other areas of human endeavor. When Creative Problem-Solving appears in upper case, CPS for short, it connotes an explicit creative process designed to deliberately engage creative thinking to resolve complex problems. CPS is a cognitive, rational, and semantic process that builds on humans' innate creative problem-solving tendencies. As a deliberate creative process, CPS helps individuals to move the production of creative breakthroughs from chance occurrence to directed thinking that improves the probability of original and valuable outcomes. This is accomplished by providing a structure that facilitates the application of creative thinking to open-ended problems. CPS provides individuals with a heuristic solution path that, once mastered, can be universally applied both by individuals and groups to more effectively and

efficiently resolve complex problems. The next section of this paper outlines the specific structure of CPS.

Creative Problem-Solving: The Thinking Skills Model

The first version of CPS to be disseminated for wide-scale use was featured in Alex Osborn's (1953) book *Applied Imagination*. One of the most popular books ever written on applied creativity methods, Osborn introduced brainstorming to the world through this publication. This seminal work described the creative process that, as an advertising executive, Osborn had tested and refined over several decades. However, while Osborn had tested the veracity of CPS and brainstorming in the business world, his dream was to start a movement that would change education. His concern was that success in life and work demanded creative thinking, as many of today's educational, business, and governmental leaders now tout (Trilling and Fadel 2009; Wagner 2008), and Osborn recognized that educational practices often excelled at undermining rather than elevating this crucial skill. Osborn offered CPS as a deliberate creative methodology that would allow individuals to more effectively apply their innate creative thinking abilities to complex problems.

Since its introduction CPS has gone through continuous improvement and evolution. Table 1 provides a summary of the variations of the CPS process that are direct descendants of Osborn's original process. For a more in-depth review of these processes, see Puccio et al. (2005). For the purposes of this paper, we will focus on the most current version of CPS called the Thinking Skills Model (TSM). Suffice it to say that one of the strengths of CPS is the fact that this deliberate process model has had a rich history through which several generations of scholars have refined and extended the work of their predecessors. As a consequence, the current version, CPS-TSM, is a beneficiary of the practical insights and wisdom that were derived from decades of experience and research.

The developers of TSM, Puccio et al. (2011), defined CPS as "a comprehensive cognitive and affective system built on our natural creative processes that deliberately ignites creative thinking and, as a result, generates creative solutions and change" (p. 43). These scholars further broke each of the key terms associated with the "CPS" into more specific definitions as follows:

Creative. "The production of ideas or options that are both new and useful" (p. 43).

Problem. "What exists when there is a gap between what you have and what you want" (p. 43).

Solving. "Taking action in some way...solving implies finding an answer or resolution to situations" (p. 44).

CPS-TSM serves as both a process and a model for applied creative thinking. Puccio et al. (2011) defined process as "a particular method of doing something, generally involving a number of steps or operations" (p. 43). As a process, CPS-TSM provides individuals and teams with a learnable system of steps that serves as a heuristic solution path for complex problems. Again, Table 1 provides a summary of the steps various scholars have used to operationalize the creative process. Focusing on CPS-TSM, Fig. 2 (Creative Problem Solving: The Thinking Skills Model) graphically illustrates the operations behind the current version of CPS. As a heuristic solution path, CPS provides problem-solvers with a rationale set of stages that move the problem-solver from the problematic present state to the desired outcome. In contrast to Stokes (2013) description of the solution path, which was mainly focused on the search for a workable solution, CPS provides a more expansive set of stages that are in keeping with comprehensive descriptions of the creative process (i.e., creativity is much more than idea production, it also involves problem construction, idea production, solution development, implementation, etc.).

Beginning with the outer layer of Fig. 2, CPS-TSM is organized into three broad stages known as Clarification, Transformation, and Implementation. These stages represent a logical progression from clarifying the nature of the problem to generating ideas that are transformed into

solutions that address the problem and concluding with the creation of a plan that moves the proposed solution into action. Each stage is comprised of two specific steps. These steps represent a movement from broader to more specific forms of thought. In Clarification the problem-solver first explores broad goals and wishes; this is called Exploring the Vision. Next, the problem-solver proceeds to Formulating Challenges. Here, specific issues and obstacles are identified that must be addressed in order to achieve the selected vision. The Transformation stage is initiated by Exploring Ideas, where the problem-solver engages in a broad search for possibilities intended to resolve the challenges identified in the previous step. This step is followed by Formulating Solutions, where the most promising ideas are refined into workable solutions. Finally, in the Implementation stage, the problem-solver shifts

his or her focus to the broader context within which the proposed solution is to be introduced. To promote success the problem-solver begins with the step called Exploring Acceptance, which is designed to facilitate an examination of the environmental factors that will either help or hinder implementation. This analysis influences the creation of an action plan, which occurs in the second step of this stage and the final step of the CPS-TSM process (i.e., Formulating a Plan).

While the above description provides a sequential overview of the CPS process, the application of the process is rarely linear. To be sure, there is a natural flow to the process, but individuals and teams can begin at any step and then flexibly apply the steps as needed. For example, if it is clearly understood what obstacle must be overcome to reach the goal, then it is advantageous to move directly into Exploring Ideas and

begin generating ideas that address the challenge. However, the production of ideas allows the problem owner to test his or her understanding of the challenge and in some cases facilitates the recognition that the wrong challenge is being worked on. When this happens the problem owner can revise the challenge statement and begin with a new set of ideas. Alternatively, if deeper analysis is required, the problem-solver can go back to the Formulating Challenges step and engage in a process of deconstructing the goal into an exhaustive list of obstacles and barriers that stand in the way of success. From here the problem owner prioritizes the challenges and returns to the Exploring Ideas step with a new challenge statement for which he or she will amass new ideas. From this point, the problem-solver can continue to move through the process until a plan is formulated and put into action.

Since CPS-TSM is a flexible process, problem-solvers should always begin with the step in the center of the process, referred to as Assessing the Situation. Puccio et al. (2011) described Assessing the Situation as the meta-step to CPS-TSM as it serves an executive function. Here problem-solvers gather data and then use insights gained from this understanding of the situation to make a decision as to where to go next in the process. For instance, if individuals or teams have already reached a conclusion as to the solution they wish to carry forward, which could be a new service, product concept, or response to a problem, then they might wish to pick up the process at the Exploring Acceptance step. Here they examine the context or contexts in which they hope to introduce their new solution, in order to anticipate forces that will help or hinder adoption.

CPS: A Model for Deconstructing Creative Thinking

Returning to an earlier point, CPS-TSM serves as both a process and model for applied creative thinking. The overview of the steps of CPS-TSM, and how they operate, relates to the use of CPS-TSM as a process. For a more expansive description of the application of this applied

creativity process, see Puccio et al. (2011). As a model of applied creative thinking, CPS-TSM delineates the thinking skills that make up creative thinking. In fact, this version of CPS is the first to articulate the cognitive skill that are necessary for successful creative thinking to occur and in particular the thinking skills that contribute to the effective application of creative thinking to problem-solving.

According to the updated version of Bloom's taxonomy of thinking (Anderson and Krathwohl 2001), creativity is the most complex form of thought humans can achieve. As a complex form of thinking, creativity must be comprised of a range of subskills. Like an athlete must master specific skills to achieve success, so must a creator master a range of skills to produce truly creative outcomes.

As a model of applied creative thinking, CPS-TSM associates a different thinking skill with each step of the process. In other words, each of the seven steps requires the problem-solver to adopt a new mode of thinking. When taught as a process, CPS-TSM helps individuals to develop the competence to more fluidly engage in each of these thinking skills. In short, CPS-TSM helps learners to master the nuances of creative cognition. Table 2 provides a summary of the thinking skills associated with each step of CPS-TSM.

Recent work in the area of emotional intelligence has highlighted what humans have intuitively recognized for centuries; our emotions and attitudes serve to promote or undermine our thinking (Brackett 2019; Goleman 1995). Within the field of creativity, there has been much research into the feelings and attitudes that promote higher levels of creativity. Borrowing from this literature, CPS-TSM postulates the affective skills that support each of the seven cognitive capacities. Put simply, it is believed that these affective skills modulate the specific cognitive skills found in CPS-TSM (see Table 3 for the CPS-TSM affective skills).

The Dynamic Balance in CPS: Balancing Divergent and Convergent Thinking

While the stages and steps of CPS have been variously expressed through the years, one

Creative Problem-Solving, Table 2 Some key cognitive skills associated with CPS

Step	Assessing the Situation (executive step)	Exploring the Vision	Formulating Challenges	Exploring Ideas	Formulating Solutions	Exploring Acceptance	Formulating a Plan
Purpose	1. To describe and identify relevant data 2. To determine next process step	To develop a vision of a desired outcome	To identify the gaps that must be closed to achieve the desired outcome	To generate novel ideas that address important challenges	To move from ideas to solutions	To increase the likelihood of success	To develop an implementation plan
Cognitive skills	Diagnostic thinking	Visionary thinking	Strategic thinking	Ideational thinking	Evaluative thinking	Contextual thinking	Tactical thinking
	Making a careful examination of a situation, describing the nature of a problem and making decisions about appropriate process steps to be taken	Articulating a vivid image of what you desire to create.	Identifying the critical issues that must be addressed and pathways needed to move toward the desired future	Producing original mental images and thoughts that respond to important challenges	Assessing the reasonableness and quality of ideas in order to develop workable solutions	Understanding the interrelated conditions and circumstances that will support or hinder success	Devising a plan that includes specific and measurable steps for attaining a desired end and methods for monitoring its effectiveness

constant across all versions of CPS has been the intentional balance between divergent and convergent thinking within each step of the respective process. Indeed, the hallmark of CPS has been the separation of divergent and convergent thinking, with the application of divergent thinking preceding the use of convergent thinking. Humans developed the ability to direct their thinking roughly 100,000 years ago, and it is this ability that can empower us to take charge of the creative process. Figure 3 provides a visual depiction of the dynamic balance between divergent and convergent thinking. Divergent thinking, represented by the top portion of the diamond, involves a broad search for many, varied, and original options. Generally, and by nature, this search begins with the production of options that are already familiar, known, and not highly novel, but through persistence individuals are able to move their thinking into new areas of discovery. Both research and practice have demonstrated that four guidelines are useful in promoting more effective divergent thinking. These guidelines are *Defer Judgment*, *Go for Quantity*, *Make Connections*, and *Seek Novelty*.

The bottom portion of the diamond graphically illustrates convergent thinking, which is the ability to screen, select, and develop the most promising options. Here the wide range of options produced during the divergent thinking phase are reviewed and winnowed down to those options

that represent the greatest value relative to that step of the CPS process. New areas of discovery, those novel ideas generated during the divergent phase, then must be successfully introduced into existing situations and paradigms. Like divergent thinking, four guidelines are useful in promoting effective convergent thinking: *Apply Affirmative Judgment*, *Keep Novelty Alive*, *Check Your Objectives*, and *Be Deliberate*.

The balance between divergent and convergent thinking is essential to effective creative problem-solving efforts (see Fig. 3). Moreover, it reflects the evolutionary process found in nature, which is the balance between the production of novel variations and then the selective retention of those variations that prove to be most adaptive (Darwin 2003). Indeed, a recent study of problem-solving in groups highlighted that those groups who separately engaged in divergent and convergent phases of thought were significantly more fluent, flexible, and original in their idea production than groups that muddled these two basic forms of thought (Puccio et al. 2018). Additionally, teams that were guided by the process of separating divergent and convergent thinking (as shown in Fig. 3) produced solutions judged as creatively superior to those produced by teams who, by nature or habit, mixed divergent and convergent thinking during their problem-solving session.

The balance between divergent and convergent thinking represents a crucial polarity within the creative process. A polarity is the effective balance or integration of two concepts that are inherently value neutral. While at a glance they may appear to be contradictory, in practical terms they are dependent upon one another to achieve a greater purpose or goal. For example, work and play is a polarity, and when humans do not effectively integrate these two concepts in their lives, problems can occur (Miller 2004; Puccio 2017). Intriguingly, in the field of creativity Csikszentmihalyi (1990) has noted that the creative personality is full of contradictions, or what we see as polarities. Creative people, according to Csikszentmihalyi, are both playful and disciplined, humble yet proud, extroverted and introverted, passionate yet able to be objective. We would argue that this polarity between

Creative Problem-Solving, Fig. 3 Dynamic balance: divergent & convergent thinking. (Source: Puccio et al. (2012). Reprinted with permission)

divergent and convergent thinking represents a process polarity that is central to creative productivity and to the creative personality (Csikszentmihalyi 1996; Parnes and Biondi 1975).

The application of polarity management theory (Johnson 1996) to the concepts of divergent and convergent thinking reveals important implications and insights relative to the balance or imbalance between these two fundamental forms of thinking. Polarity management theory holds that there are upsides and downsides that are inherent to both poles. Effective management leverages the positive aspects of the respective poles and mitigates the downsides. Poor management, such as becoming preoccupied with one pole over the other, results in negative consequences derived from that particular pole. Using our previous example, the work-play polarity might indicate that too much time at work can lead to burnout; conversely, excessive time engaging in play can interfere with the production of sufficient income.

Figure 4 (Polarity between Divergent & Convergent Thinking) provides a graphic summary of the dynamics of polarity thinking as applied to the interplay between divergent and convergent thinking. Either form of thinking, taken to an extreme, results in negative consequences. Effective creative problem-solvers know how to balance divergent and convergent thinking so that they can maximize the upside of both forms of

thought. To achieve balance, it is helpful for problem-solvers to recognize the early warning signals that they are spending too much time in one pole and thus risk slipping into the downside of that pole. We would argue, and research bears it out, that effective problem-solving relies on an ability to balance these two forms of thinking. Again, one of the overarching skills taught through CPS training is the capability of moving fluidly through the steps of CPS by effectively balancing divergent and convergent thinking in every step along this heuristic solution path. The result is not only the unhindered ability to generate possibilities but also to recognize among those possibilities which ones hold the greatest promise to resolve a predicament or to seize a new opportunity.

Summary: A Conceptual Map of Creative Problem-Solving

To summarize our review of CPS, we close by providing a conceptual map of CPS (see Fig. 5, Conceptual Map of CPS). Using levels of abstraction, moving from broad to more concrete concepts, this map is designed to show how CPS is situated within the broader field of creativity studies. We offer this map as a way of summarizing the information outlined in this entry. At the highest level of abstraction is the domain of creativity studies. The next level down reflects what are

Creative Problem-Solving, Fig. 4 The Polarity between divergent & convergent thinking. (Source: @ G. Puccio, 2019. Used with permission)

Creative Problem-Solving, Fig. 5 Conceptual Map of CPS. (Source: @ G. Puccio, 2019)

commonly referred to as the facets of study within this domain. This paper has focused on one facet, deliberate creative process methodologies, and within that facet one process framework called CPS-TSM. As a model for creative thinking, CPS-TSM involves two broad executive skills, one cognitive (i.e., meta-cognition) and one affective (i.e., mindfulness). These executive skills are necessary to operationalize two macro-skills, divergent and convergent thinking, which are featured in each step of the CPS process. As CPS-TSM intentionally invokes creative thinking, this creativity model can be further deconstructed into the micro-skills that comprise this overarching higher-order thinking skill. Finally, as a deliberate creative process, people can learn tools that enable them to effectively engage in these more specific forms of thinking. While some become enamored with learning tools, it is crucial to recognize how these concrete methods fit into the constellation of creativity. Like a marionette's string, a single tool pulls on only one appendage. To fully grasp the possibilities that can be derived from the marionette, and from the act of creativity, one must understand the interrelationships within the complete system.

Creative Self-Efficacy

Ross C. Anderson

University of Oregon, Eugene, OR, USA

Creative Engagement Lab, Eugene, OR, USA

Abstract

Creative self-efficacy is a person's prospective belief that they can organize and execute the necessary actions for a successful creative process, leading to a successful creative product within a specific context. Creative self-efficacy differs from other types of self-efficacy because it is a generative and innovative type of confidence. Creative self-efficacy

is not only necessary for persistence once creative efforts are launched, it is also key for choosing to take the risk of engaging in a creative task from the onset. This entry digs into these complexities within creative self-efficacy, specifically, by building on a socio-cultural perspective and drawing connections between creative self-efficacy and the possible as a field of inquiry.

Keywords

Future thinking · Agency · Collectivist · Growth mindset · Metacognition

Introduction

Creative self-efficacy derives from the late Albert Bandura's (1997) general concept of self-efficacy as a motivational driver for people across a variety of contexts. Self-efficacy builds on the premise that if someone doesn't feel very capable of being successful at something, they aren't likely to feel very motivated to try or persist. As such, researchers consider self-efficacy to reside alongside cognitive abilities as the key factor shaping the effectiveness of human functioning (Karwowski et al. 2013).

Bandura defined self-efficacy as a person's belief that they can be successful organizing and executing actions in a particular setting and on a specific task. Self-efficacy can be considered as general self-confidence in a broader context, such as in school or at work, and still play a role in important outcomes, such as school engagement and resilience (Amitay and Gumpel 2015; Anderson et al. 2019). However, Bandura promoted task and domain specificity in conceptualizing self-efficacy as more immediately consequential for human motivation for action. A sense of efficacy in oneself does not develop or sustain in isolation but rather through interaction and observation in the world around us. In this way, the term itself may be incongruous with the nature of the concept and somewhat misleading – it may emerge from the self, but it is influenced by others. Social cognitive theory (Bandura 1986) emphasizes the shaping of

efficacy beliefs through vicarious experience and observation of others, and recent research has illustrated how the self-efficacy a young person carries in a given domain, such as science, is deeply interwoven with the experience of others like them (Kim et al. 2021).

This entry digs into these complexities within creative self-efficacy, specifically, by building on a sociocultural perspective (Glaveanu et al. 2019) and drawing connections between creative self-efficacy and the possible as a field of inquiry. Several connections will be discussed. First, self-efficacy is prospective, so creative self-efficacy is naturally future oriented. Second, creative self-efficacy is momentary and hypothetical, involving a person gauging their confidence for an imagined task or setting that may never happen, which could immediately change depending on the experience and exposure that comes next. Third, because creativity doesn't exist in a vacuum creative self-efficacy is social and cultural as well as personal, meaning that a person will judge their confidence to be creative in a specific context based on implicit or explicit criteria about creativity and based on the experiences of others like them. Still, at the individual level, creative self-efficacy is a largely private and internal dialogue that will consider a variety of other factors that construct our identities across domains of life.

Fourth and related to the previous point, creative self-efficacy does not guarantee actual success in creative performance and accomplishment when creative efforts face the constraints and judgments of the world. These four connections link directly to imagined possible selves, worlds, and futures. While creative self-efficacy links to a person's past experiences and general self-concept (Anderson and Haney 2021; Beghetto and Karwowski 2017), the power of imagining successful creative efforts of a future self may be one the most powerful mechanisms to leverage human potential.

The Prospective Nature of Creative Self-Efficacy

As Mathisen and Bronnick (2009) pointed out, Bandura originally recognized the natural link

between creativity and self-efficacy in his origination of the concept:

Innovativeness requires an unshakable sense of efficacy to persist in creative endeavors when they demand prolonged investment of time and effort, progress is discouragingly slow, the outcome is highly uncertain, and creations are socially devalued when they are too incongruent with pre-existing ways. (Bandura 1997, p. 239)

Creative self-efficacy is a person's prospective belief that they can organize and execute the necessary actions for a successful creative process, leading to a successful creative product within a specific context (Tierney and Farmer 2002). Creative self-efficacy is not only necessary for persistence once creative efforts are launched it is also key for choosing to take the risk of engaging in a creative task from the onset. It is the foundational belief that future success is possible. Creative self-efficacy can help motivate people to approach, rather than avoid, the kind of risk-taking necessitated for creative engagement by highlighting the possibility of success rather than overemphasizing the likelihood of failure. In this way, creative self-efficacy is a future-oriented fuel for the possible. Research has illustrated the potential to develop creative self-efficacy with careful, focused, and intentional practice (Anderson et al. 2022a; Mathisen and Bronnick 2009). Self-efficacy is about imagining one's success rather than measuring – and potentially limiting – oneself based on past performance or comparison with others.

The Momentary Phenomenon of Creative Self-Efficacy

Creative self-efficacy differs from other types of self-efficacy because it is a generative and innovative type of confidence. There is a risk of failure in most, if not all, endeavors; however, the risks and uncertainty within creativity are especially provocative (Beghetto 2019). The possible within creative self-efficacy must confront uncertainty. This combination likely contributes to the context specificity and ephemeral nature of creative self-efficacy, where confidence in our skill and belief in creative success interact with the ever-changing circumstances in the sociocultural setting and

task. This evolving nature of creative self-efficacy may be in part why it correlates weaker with actual creative performance or creative achievements than with other creative self-beliefs and markers of creative identity (Haase et al. 2018). In fact, meta-analytic research suggests that the weak relationship between self-efficacy and creative performance does not improve substantially when there is greater specificity about the target and focus of those self-beliefs. Creative self-efficacy is about action and imagined success for oneself, not necessarily to satisfy the criteria set by others. Though creative self-concept can be framed, in part, by social comparison (Anderson and Haney 2021), creative self-efficacy is most often framed as self-reflexive. In that way, creative self-efficacy is personal, like a form of self-coaching.

In this way, creative self-efficacy may develop across experience in a domain as a person learns more about themselves and what is possible within that domain. The development of early confidence to be creative in a new domain likely grows out of the mini-c level of personally meaningful and important creativity (see the Four C Model of creativity; Kaufman and Beghetto 2009). Creative self-efficacy would then grow more robust across different aspects of a skill or domain to activate the resources to achieve Pro-C or Big-C creativity that affects others and even has lasting change on the world. The fact that creative self-efficacy promotes the agentic beliefs to take a risk and try something new is what matters most and why creative self-efficacy may indeed be so key to the functioning of our creative agency.

The underlying foundational role of creative self-efficacy and its progressive development across creative experiences was an important finding in recent research on teachers' creative development in the classroom (Anderson et al. 2022a). In related work, when teachers developed creative self-efficacy for their teaching alongside other creative self-beliefs (e.g., value of creativity for students and growth mindset about creative development), they also developed more resilience, joy, and well-being in teaching (Anderson et al. 2022b). Not surprisingly, teachers who felt stronger creative self-efficacy in teaching experienced less anxiety facing creative challenges (Anderson

et al. 2021). In the moment we face a creative challenge, self-efficacy likely serves as a protective factor for the possible. It provides courage, grace, and strength to step toward the discomfort of uncertainty rather than to fold to anxiety and run and hide.

Collectivist Creative Self-Efficacy

Importantly, Bandura's work on self-efficacy originated in observational learning – he found that human learning of norms and skills occurs through observations of others in various contexts (Bandura 1986). Mastery experiences are key to self-efficacy development, but humans also develop efficacy beliefs by observing the modeling and success of others. Similarly, scholars have recently emphasized the inseparable social and cultural aspects that shape our beliefs of and experience in creativity (Glaveanu et al. 2019). Bridging those perspectives, the self-efficacy we feel for our creative potential must be considered in relationship to others and the world around us. The balance of the self and others may depend on our cultural orientations. Cultural psychologists use individualistic versus collectivistic orientations to distinguish whether people emphasize personal or social identities (e.g., Markus and Kitayama 1991). The same distinction should be considered when looking at how creative self-efficacy develops and how our individual creative experiences may play a role in others' development of creative self-efficacy and vice versa. What you believe is possible for yourself naturally shapes what I believe is possible for myself.

Bandura (2018) called the role of vicarious experience and modeling of others in shaping our self-beliefs and overall sense of agency, proxy agency. He suggested that proxy agency shapes the social, cognitive, and motivational development of the self. The power of proxy agency may depend on how well people relate to one another based on shared experiences and culture. These factors were recently on display in a study on the development of science self-efficacy of racially diverse high school students. Their proxy agency grew from the experience shadowing undergraduate mentors, hearing their stories of resilience, and learning their strategies to take control of their

choices (Kim et al. 2021). Proxy agency may also have a reciprocal and reaffirming quality for people sharing their experiences, building their self-efficacy further. From a collectivist orientation, the development of one's creative self-efficacy, in particular, may be inseparable from the proxy agency modeled by others, who they can relate to socially and culturally. For instance, teachers shared the encouragement and confidence they felt from hearing about the creative ideas and risk-taking that other teachers were trying themselves (Anderson et al. 2022a). Encouragement from others also predicted the creative self-efficacy of college students in another study (Puente-díaz and Cavazos-arroyo 2017).

Motivating Action Not Guaranteeing Success

Creative self-efficacy is needed to persist in creative effort because hindrances, risks, and failures are likely (Tierney and Farmer 2002). However, research has also shown that creative self-efficacy is not enough to guarantee that creative efforts will be successful (Haase et al. 2018). Holding self-awareness about creative strengths and areas for growth alongside understanding of context and strategy may be just as important to put that self-efficacy to work (Anderson and Haney 2021; Beghetto and Karwowski 2017). That creative metacognition can be cultivated and may be an important part of transferring creative self-beliefs and strategies across different contexts.

Creative metacognition begins, though, with a growth mindset that suggests creative development is possible with practice and effort, rather than determined by a fixed level of creative ability (Lench et al. 2015). Not surprisingly, growth mindset beliefs about creative ability and creative self-efficacy are highly related in research (Hass et al. 2016). When a person develops a greater understanding about creative strategies within a specific context, such as in teaching, it seems to be more likely that they will see creativity through a growth rather than fixed mindset, providing a launching point for their creative self-efficacy to take shape (Anderson et al. 2022a).

Self-Efficacy as Pathway to Possible Future Self

A recent taxonomy of future thinking includes four basic forms of future thinking: (a) *simulation*, or the construction of a specific mental representation of the future; (b) *prediction*, or the estimation of the likelihood of a future outcome; (c) *intention*, or setting of a goal; and (d) *planning*, or organization of steps for achieving a goal (Szpunar et al. 2014). This taxonomy may be helpful for future work in creative self-efficacy. Creative self-efficacy can be considered alongside all four of these forms of future-oriented thinking when considering its role in shaping motivation toward specific actions and a future self. Additionally, it has been proposed as a self-belief underlying general creative ability facing nonspecific creative challenges (the semantic level in future thinking) and as a self-belief dictated by the specific domain, setting, or task (the episodic level in future thinking; Szpunar et al. 2014; Haase et al. 2018).

Though more research is needed, the potency of creative self-efficacy to motivate actual creative action and actual creative performance may be shaped in part by the level of specificity and alignment of those beliefs with the context, setting, and task demands. For instance, will a person's self-efficacy to come up with original uses for a common object have the same motivational power toward action in a furniture design class as their self-efficacy to come up with a new design for a living room chair? Creative self-efficacy may also differ in its influence depending on what form of future thinking it targets related to creative experience. For instance, do creative self-efficacy beliefs related to predicting future success in a creative challenge contrast or compete with a person's confidence to create and evaluate their plans to achieve that goal? Which self-efficacy beliefs are more likely to lead to the kinds of creative risks that result in a creative disruption or breakthrough?

To learn more about how creative self-efficacy functions in the shaping and pursuit of the possible, future research can parse out what aspects of the creative process may require the strongest self-efficacy to initiate and sustain engagement in creative efforts. Following Bandura's original encouragement (Bandura 1997), the development of

creative self-efficacy as a future-oriented phenomenon in the human experience and as a field of study must continue cultivating greater precision and specificity to become a powerful driver of the possible.

Summary

Creative self-efficacy is a powerful motivational fuel for the possible in creative thought and action. This entry presents four components of creative self-efficacy that describe the path of research taken thus far and suggest future directions related to the possible. Creative self-efficacy is prospective and naturally future-oriented. Creative self-efficacy is momentary and hypothetical and therefore context dependent. Creative self-efficacy is at once personal and private and existing outside the self, affected by social and cultural factors including the vicarious experience of others. Creative self-efficacy does not equate to actual creative accomplishment, but it opens door to that possibility. By framing creative self-efficacy through different components of future thinking, creative self-efficacy could become an anchor to the possible as a field of inquiry.

Abstract

This entry approaches creativity as a possibility-testing and possibility-expanding phenomenon. It starts with a critical consideration of the definition of creativity in psychology, arguing that a study of the possible and impossible gets us closer to the nature of the creative

process. Then it proceeds to analyse the relation between (im)possibility and creativity at the level of actors, actions, audiences, artefacts, and affordances. In each case, the focus is on (a) how these elements contribute to the engagement with the possible enabled by creative expression and (b) how they are transformed by the possibilities and impossibilities discovered along the way. The entry ends with reflections on the relationship between creativity and other possibility-expanding phenomena.

Keywords

Creativity · Possibility · Five A's model · Actors · Actions · Audiences · Artefacts · Affordances

Introduction

Creativity is typically defined in psychology as the process leading to new, original, and valuable outcomes (for a broader discussion see Runco and Jaeger 2012). This basic definition, while useful for testing and measurement, is largely incomplete. We don't learn anything from it about the individual or groups doing the creating or the nature of the processes and contexts that generate and integrate, respectively, these special outcomes (for a more extensive critique, see Glăveanu 2014). Most of all, it can mistakenly give the impression that creativity is mostly concerned with novelty, originality, and value. Taken separately, each one of them are characteristic for something else: novelty is central for the experience of surprise, originality for things that are rare and unique, value defines the conventional. Even taken together, the three criteria – or two, if novelty and originality are grouped – don't do justice to the richness of creativity and its meaning for human existence and for society.

In this entry, I propose to explore the phenomena that lie “behind” surface indicators such as novelty, originality, and value and, in doing so, to tackle the deeper question of what creativity is ultimately *for*. What are we actually doing when we are creative? This question can be answered on many levels as people become creative for a variety of reasons. We

create in order to survive, to thrive, to express ourselves, to gain the recognition of others and, yes, to generate things that are new and useful. But what we essentially do through our creative acts, I argue here, is *engage* with and *expand*, more or less markedly, the space of the possible for our thinking, action, and way of being in the world.

Creativity, at its core, is the process through which we bring something that didn't exist before into existence. In other words, we materialize what is possible, even when the discovery of possibilities happens through the creative process itself (Vallée-Tourangeau and March 2019). As part of creative action, we venture beyond what is given in the "here and now" and enrich it with what could or might be, with the "not-yet-here," the "elsewhere," and the "nowhere" of imagination (Jovchelovitch et al. 2017). The defining characteristic of creativity, then, is not captured by the properties of its outcomes as much as it is by the nature of its process and this process, I propose, is at once possibility testing and possibility expanding. With this lens on, I will discuss as follows different interdependent "components" of the creativity system represented by actors, actions, audiences, artefacts, and affordances (for details about this 5 A's model, see Glăveanu 2013). For each one, the focus will be on: (a) how they contribute to the engagement with the possible enabled by creative expression and (b) how they are transformed by the possibilities and impossibilities discovered along the way. The entry ends with reflections on the relationship between creativity and other possibility-expanding processes.

Possible Actors

With the notion of "actor," I refer to the individual, group, or community that initiates a creative process. Actors are, therefore, at the center of creative agency without denying the fact that objects can also be considered agents (Latour 1991) and that, ultimately, the agency of human and nonhuman actants equally depends on their interaction (what I have previously called "co-agency"; see Glăveanu 2015a). I prefer, however, the notion of actor here to those of agent or

actant because it captures, at least in the case of human beings, the social and cultural dimension of creative people and communities. Actors exist, by necessity, within a field of social relations that both enable and constraint their horizon of possibility. At any moment in time, an actor's agency and sense of possibility is shaped by his or her interactions with others, within a given material and cultural environment. While creative people might be considered to have a wider sense of what is possible to achieve, this doesn't mean that they are faced with less constraints; on the contrary, barriers and obstacles play an important role for the creativity of the person and, when not directly available, they tend to be self-imposed (Stokes 2005).

This creative agency is experienced by actors differently depending on age, life, and cultural context. One and the same person will have different perceptions of what is possible and impossible given their changing goals and concrete interactions. But these experiences of possibility and impossibility also accumulate over time within the self and create *expectations* as to what can come easily, what would be hard to accomplish, and what is altogether unachievable. Such accumulations are discussed in the creativity literature often in terms of identity, self-concept, and mindsets (see Karwowski and Kaufman 2017). They designate a series of self-beliefs or perceptions of one's abilities, particularly when it comes to creative expression. Some people will approach problems with a creative attitude, ready to see new opportunities for self-expression, while others will feel stressed or even demoralized by a given obstacle. And these perceptions are likely to be domain and even task specific (Kaufman and Baer 2004), leading to a rich and unique tapestry of possibilities and impossibilities for the self, woven not in solitude but in close relation to other actors.

Indeed, creative actors' engagement with the possible is rooted in their life experience which grows, in turn, out of their social, economic, and political context. Members of privileged groups in society tend to develop more easily a creative identity or, at the very least, have their creativity recognized by others. In contrast, marginal and oppressed groups struggle for recognition and visibility, including the chance to develop new

possibilities for themselves. While the latter might display, on a daily basis, more creativity than the former due to the constraints they come up against, this creativity is either unrecognized or downplayed (see Kaufman and Glăveanu [in press](#)). The most serious consequence of this dynamic is the internalization of impossibilities and, with it, the extinction of the natural drive to create, grow, and improve one's situation. In this sense, a study of creative actors should always be connected with that of (im)possible actions for them within society.

Possible Actions

Action is the cradle of possibility (see Glăveanu [in press](#)) in the sense that our awareness of what is possible and exploration of it necessarily depend on action. This doesn't mean that action is reduced to its behavioral dimension; thinking is a kind of action (Wertsch [1998](#)) just like imagination is (in fact, Vygotsky referred to it as internalized play; Smolucha [1992](#)). What is distinguishable about the study of human action is precisely its focus on the coordination between psychological and behavioral facets. The former includes goals, intentions, feelings, and symbolic forms of understanding, the latter is expressed in gestures, postures, and practical forms of doing. Human action is, at all times, *culturally mediated*, as we use tools and concepts to guide its course. This mediation helps us open up and close down various spaces of possibility. Before we act, we envision multiple outcomes; as we act, we have chosen one to materialize or, in some cases, let fate decide; after we have acted, we observe the outcome that actually came to be and its set of (im)possibilities for future action.

This dynamic between doing and undergoing, between acting on the world and perceiving the consequences of our action, has been widely discussed by John Dewey in relation to art (see Dewey [1934](#)). It is also much more widely applicable, as a framework, for other domains of creative activity (Glăveanu et al. [2013](#)). What this simple framework is missing, however, is a better understanding of how the

sense of possibility shapes our course of action and how action, in turn, redefines what is possible at every moment. In many ways, human action can be read in terms of the dynamic between potentiality and actuality – what exists in potential guides our relation to the actual and what becomes actual recreates, for us, a new sphere of the potential. Possibility-testing, trial and error, and experimentation processes are all specific for creative action, even in the case of “conceptual” creators (Galenson [2011](#)). It is because one can never be fully certain of the outcomes of human action that the unexpected is necessarily embedded within it. And, with it, a new horizon of unforeseen possibilities (and impossibilities) arises. To act creatively means, thus, to make the most of the accidental aspects of our actions by being attentive to the situation as it evolves and attuned to others in what Dewey called the experience of “undergoing.”

The range of possible actions in creativity isn't reducible, however, to acts of making. As an ecology of relations, engaged in by various actors and their audiences, creativity depends equally on making and on symbolic interpretation. This is why, as we shall see next, audiences have a crucial role to play in the creative process – they can give an existing creation new meaning and a new “life” by noticing more of what is possible with it or because of it than even the initial creator did. And then, there is also an important part played by *failure* in the process of creativity (see also Tahirsylaj [2012](#)). Moments of uncertainty, risk, and apparent failure can become the seeds for the discovery of previously unperceived (and sometimes unconceivable) potentialities. Failed actions not only help us come against what is impossible – given that things don't work, break, or generally resist our intentions and vision – but, in making us aware of an impossibility, they often reveal pathways to overcome it.

Possible Audiences

It would seem, at first, that actors and their actions solely define the field of possibility. But

creative actions are, most of all, *interactions*, in the sense that other people and material tools respond or react to, respectively, the acts and intentions of the creative actor. Audiences emerge, thus, as central to engaging with the possible as *cocreators* of the phenomenon we call creativity (see also Vygotsky 1990). By audiences I don't mean here a generic, anonymous public. I refer to each and every person or group the creator is in dialogue with, explicitly or implicitly, as part of a process of creating. These people can be family members, friends, peers, mentors, competitors, critics and, indeed, more distant publics the creator is not directly in contact with, but that still exert their influence on his or her thinking.

The role of audiences in creativity is, as such, not reduced to passive receptors but active contributors to the preparation, production, and evaluation of creative artefacts. In each case, the view, perspective and expertise of other people become essential. Nothing is created in complete solitude and even one's most personal and unique ideas grow out of a personal history of living within society, learning and using a language, and becoming part of a culture (or more). Audiences help creators engage with the possible by showing them that other ways of thinking or acting in the world exist or can be conceived. It is the *difference* between self and other, between actors and audiences, that ultimately represents the engine of creative expression. Without this difference, we would live in worlds in which there is no possibility of being surprised, of learning something new, or of witnessing any emergence in the sphere of society. Differences of perspective nurture the possible and reflective dialogues between these perspectives are essential for the creative process (Glăveanu 2015b). These dialogues, or the acts of putting different perspectives in relation to each other, fuel our creativity and imagination by leading to new perspectives and by making us aware that we hold a perspective *among many* possible others. It is this experience of one's position and perspective in the world as one among many that makes creative actors wonder what else might

be there, what could be possible above and beyond the things we perceive and envision (for details see Glăveanu 2019).

Audiences don't have to be physically present in order for these possibility-expanding processes to take place. The perspective of other people can be taken by us imaginatively and we are all in "dialogue" with the ideas of mentors and role models, including some which have long past or we have never met in person. And there is yet another interesting relationship for creativity and that is the one with *future audiences*. Creative actors often ask themselves – or, if not, should be taught to ask themselves more – how their actions and artefacts impact other people, people who are not present, who don't have a voice, and especially the next generations. Leaving one's mark on the world is exciting, but its creativity will depend on how it serves those from a future that is yet to come (for the relation between creativity and wisdom see Sternberg & Lubart 2001).

Possible Artefacts

Artefacts participate in different ways to the creative process. On the one hand, various artefacts are used to create, from sophisticated technologies to the more traditional pencils, paintbrushes, and colors. On the other hand, artefacts designate the outcomes of a creative process, its visible or materialized conclusion, which doesn't mean that these outcomes necessarily have to be objects – the products of creativity can be symbolic or ideational or embodied in events or performances. Ultimately, by calling these end products "artefacts," we point to the fact that they have a cultural basis and contribute, in turn, to the broader culture of the creative actors and their audiences (Glăveanu 2011a).

It would seem, at first glance, that once the creative process is complete and the artefact "stabilized" in a certain form, possibilities have ended. If anything, artefacts come to represent the fossilized expression of what was possible but became actual and fixated in a given form. This understanding is misleading, however, on two accounts. First of all, artefacts can and do

initiate new creative processes in the case of creators, who can be inspired to pursue the development of a series, and users, who might be prompted to adapt the artefacts to their own needs and effectively recreate them (see, for instance, discussions of user innovation, see Von Hippel 2005). On the other hand, an artefact itself is never a fully finished or stabilized form. This is captured by how difficult it is for most creators, especially in the fields of art and design, to say when something is “done.” And even when, by necessity, a creative outcome is released as final, its interpretation and reinterpretation in society keep it creatively “alive” and open to a wide range of possibilities.

These ideas have been captured in the literature by concepts like “*boundary objects*” and the “*open work*.” The former designates those artefacts that are situated at the intersection between multiple communities and related to differently by them (Star and Griesemer 1989). Most well-known products of creativity tend to address various users and interpreters and to stimulate debate, even controversy. It is through this clash of perspectives that new possibilities emerge, either for redefining the creation or generating other artefacts with original properties. The notion of “open work” originates in the writing of Umberto Eco (Eco 1989), who noted how some artefacts – especially artworks – are never meant to be finished. They are meaningful and creative precisely because they remain open to interpretation, somewhat ambiguous in nature, and versatile in use. For example, a musical score can be seen as the standard that allows no deviation but, at least historically, it gave creative actors a set of general guidelines from which they could improvise and to which they could add. Not all creative artefacts are equally open to the possible by design, but all of them *could* be if audiences are free to reinterpreting what has been created (see also the entry on “► [Creative Inconclusiveness](#)” in this encyclopedia). For this to happen, the dominant culture of deference to creators and their products needs to be replaced by one that values co-creation and a playful interaction with the ideas and objects produced by others.

Possible Affordances

Creativity is not reducible to ideation or insight alone and not even best represented by it, despite the light bulb being one of the most common symbols for the creative process (Glăveanu 2011b). This kind of representation is wrong on several accounts. First of all, it seems to suggest that the essence of creativity is “getting the idea” which, in reality, is part of a much more complex process that involves doing and undergoing as well as testing various possibilities (see the section before on “[Possible Action](#)”). Second, the moment of insight is depicted as psychological and individual in nature. It takes place “inside the mind” of creative people with little help from the environment, social, or material. I discussed above, especially in relation to audiences, how important the role of others is for creative expression. A further reflection is needed about the part played by materials in creative work.

Most creative actions are highly *embodied* and make use of a wide range of objects or tools. In other words, their expression is physical and material as much as it is psychological or mental (and, in fact, the two are sides of the same coin). The psychology of creativity has been extensively concerned with creative cognition and ideation (see Ward et al. 1995) and much less so with the materiality of creation. To properly unpack the latter, we would need theories that consider the interaction between person and objects as bidirectional and focus on their relationship rather than each “term” taken separately. The notion of *affordance* goes a long way in this regard. Initially coined by Gibson (Gibson 1986), affordances designate action potentials for our action or, put differently, what it is possible for us to do in relation to the objects surrounding us. Whether an object “affords” a certain course of action or not is immensely important for creativity (see Glăveanu 2016) and, more broadly, for our understanding of the possible (see the Affordance entry in this encyclopedia).

To perceive and act upon an affordance constructs the realm of possibility for our action. Unperceived affordances, then, represent missed opportunities to do things differently. Equally,

affordances that are perceived but not acted upon, for different reasons, are possibilities not taken. Finally, there are objects with special affordances we can imagine but could never have in practice (like a square circle), that belong to the realm of the impossible. Creative action employs new and unexpected affordances to push back against impossibility and widen the space of what is thinkable and doable for the person and, in some cases, for society as a whole. A material approach to creativity and the possible, as such, builds on the relation between perspectives, or what the person “would do” in a given situation, and affordances, or what he or she “could do,” all framed by broader cultural norms (or the “should do” of the context). Sometimes these elements are in alignment, oftentimes in tension. At times, the “would” or the intention guide the action and things go smoothly; other times, the “could” of affordances reveals itself as an important constraint on the creator’s imagination. In these cases, perspectives and intentions need to be re-aligned with reality or reality changed somehow to make one’s creative vision possible.

Concluding Thoughts

In this entry, I discussed creativity as a relational and sociocultural phenomenon, an epistemological position that underlies the five A’s framework. More than this, I proposed that the nature of creativity relates less to “surface” criteria such as novelty, originality, and value, and more with the expansion (and the reduction) of the possible through the dynamic interrelation between actors, audiences, actions, artefacts, and affordances. Each one of these “elements” is constituted by its relationship with the others within a realm co-constructed possibility. In the end, these five A’s and their connections belong, at once, to the actual and the potential. They exist at any moment in time but do so within a variable set of relations that foster certain possibilities while closing down others. In this sense, adding “possible” as a qualifier for each one of the A’s is meant to emphasize the orientation toward an essentially open future that any creative system is necessarily defined by.

If the possible and its exploration occupy a central role in creativity, it’s important at the end to reflect on the place and value of creativity for human possibility. Creativity, as this encyclopedia demonstrates, is only one of many processes that relate us to the possible in our existence, ranging from imagination and innovation to wonder, serendipity, and anticipation. While it is beyond the scope of this short entry to detail the similarities and differences between these phenomena, creativity stands out among them as the process that articulates *both* becoming aware of new possibilities and acting on them. This is because, as a process, it cuts across the divide between mental and practical activity, between the rather “inner” forum of imagination and different types of thinking, and the “outer” world of implementing ideas through innovation and different forms of making. Wonder and serendipity are equally relational processes, bridging person and environment, but they have a less prominent connection with doing or making than creativity does. The possibility-testing and possibility-expanding facets of creative action are deeply integrated with each other. The first captures the experimental nature of any creative process, open at all times to the unknown, to chance and to the unexpected. The latter designates its main effect: acts of creativity and their outcomes push further the boundaries of the possible at an individual and collective level, coming up against, overcoming, and creating new horizons of impossibility for creative thinking and action to struggle with.

If we were to take the possible seriously in our theories and studies of creativity, we would pay closer attention to topics such as difference, perspective, culture, and the future in our research and practical interventions. Creative products are novel and useful, among others, and creativity does require creative people, but its main function goes beyond these issues. It concerns, first and foremost, the eminently human propensity toward the possible and the quest to cultivate it in our daily existence. And, if this is correct, the reverse must also hold: to reduce creative potential and expression, for self and others, means to diminish the possibility of existing in and acting on the world as full and dignified human beings (see also Corazza 2017).

Utopia

Definition

The notion of a “crisis of the future” was introduced by French philosopher Edgar Morin (Morin and Kern 1999). It refers to the loss of the possibility of progress, as well as a loss of a sense of what progress even means or might look like. As a result, there is a loss of *direction, of possibility, and of value* (our sense of what constitutes progress reflects what we value). This loss is exacerbated by the fear of environmental, nuclear, or other catastrophes. Positive visions of the future are replaced in popular culture by dystopian, post-apocalyptic scenarios. It is unclear how to even *think* about the future, or what might be more desirable futures. Morin interprets the term crisis in one of its original meanings, as *the moment when a diagnosis is possible*, and this is what makes his approach particularly relevant.

Background

The implications of the crisis of the future and the lack of positive (nondystopian, nonapocalyptic) visions of the future are considerable. As the Dutch futurist Fred Polak has written (Polak 1973),

The rise and fall of images of the future precedes or accompanies the rise and fall of cultures. As long as a society's image is positive and flourishing, the flower of culture is in full bloom. Once the image

begins to decay and lose its vitality, however, the culture does not long survive. (p. 19)

Symptomatic of the crisis of the future is the fact that in the first decades of the twenty-first century the term *progress* has virtually become extinct. There are few if any positive images of the future either in academic research or popular culture. What were formerly viewed as sources of progress – science, technology, and industry – are now viewed as the sources of today's unsustainable society. Utopian projects are largely viewed as the royal road to dystopias, whether in the Soviet Union or Mao's China, Jonestown or Rajneeshpuram. One significant exception, we will see, is the utopia of the free market, undergirded by the thought of Ayn Rand (Achterhuis 2010).

In the West, the broad association of the future with linear progress, technological advances, and financial prosperity appears to have collapsed (Jameson 1991; Ryan 2019). The Millennial generation is the first generation to face the possibility of being worse off than their parents economically. They are also faced with pandemics, looming environmental catastrophes, global terrorism, resurgent nationalisms, political chaos, a loss of faith in leaders and institutions, and the general sense that the world is going to hell in a handbasket (Higgs 2019). In 2009, a poll showed one in three American kids aged 6–9 (now “Generation Z”) were afraid the planet would somehow be destroyed by the time they grew up, and half said they worried it would be a bad place to live. African-American and Hispanic children worried even more than white children.

It is not only the West that is struggling with the future, but also China has seen a remarkable social and economic transformation in the last 30 years. Unprecedentedly, rapid economic growth has brought with it serious environmental issues, corruption, inequality, severe dislocation and alienation, and many forms of crime that did not exist before the economic explosion. There are questions emerging about desirable futures, given the country's radically different new direction and the

rapidity and seeming inevitability of the current changes and the elimination of the previous culture, both physically, as cities are often torn down and rebuilt, and in terms of values and a sense of community and history (Gao 2015; Jacques 2009).

Morin points out that the term crisis, which today has generally come to mean a moment of great trouble or difficulty, historically also referred to a turning point in a disease when a *diagnosis* could be made (Morin 2020). One aspect of Morin's diagnosis is that the crisis of the future is an interconnected *poly-crisis*. This poly-crisis is not limited to one factor like the economy. It affects all dimensions of human life, from the economy to the environment, from gender roles to race, and from work to play. The larger context of the crisis of the future, and arguably one key reason for its pervasiveness and its radical nature, is the current global transition between two ages. We are between stories: One age described variously as "modern" or "industrial" appears to be ending, and no new age or new stories have emerged as yet. This absence can be seen in the ways scholars have described current times using the prefix post-. Terms like *postindustrial* and *postmodern* have been in circulation since the 1970s. The prefix post- indicates not only the acceptance that one age is ending, but also the inability to fully articulate the emerging age. During this transition phase, this *interregnum*, life has gone from being solid to liquid (Bauman 2007). It has become postnormal (Sardar 2010, 2015): Everything seems upside down, nothing makes sense anymore. There is a closing down of possibilities, but it seems no new possibilities have opened up.

How Can I Miss You if You Won't Go Away?

Why does this crisis of the future persist? Why has it been so hard to get beyond "post-"? The crisis has to be contextualized in the larger historical moment, the end of the modern era, and the transition between two eras or epochs. Momentous historical transitions like this do not happen

overnight. It should also be noted that the notion of a transition time may be familiar to some intellectuals, activists, and in some New Age circles, but it has not penetrated the political or the popular discourse in quite the same way. Second, the transition is particularly momentous. The impact of technological changes has been dramatic. The Internet and automation are just two notable examples. Arguably even more dramatic is the challenge to humanity's own self-understanding: What does it mean to be a human being at the opening of the twenty-first century? As we shall see, there are, in broad strokes, two very different and opposed views.

A strong global cultural trend that has been called a "silent revolution" of value change has been in motion since the 1960s. It is described in this way:

The trajectory of value change first became evident in Western societies during the early 1970s, bringing an era of student protests. This cultural revolution was expressed through shifts toward social liberalism in mainstream left-wing political parties, as well as the rise of Green parties, and the mobilization of new social movements advocating environmental protection and fighting climate change; LGBTQ rights to employment in the military, adoption, and same sex marriage; civil rights for minorities like the Black Lives Matters movement; feminist networks with global mobilization on behalf of gender quotas in elected office; anti-domestic violence, and anti-sexual harassment, international assistance for humanitarian disasters and economic development, and human rights around the world. (Norris and Inglehart 2019, pp. 94–95)

The silent revolution challenges profound aspects of humanity's very sense of itself: humanity's relationship to nature, gender, race, and ethnicity. It further challenges the question of what kinds of relationships are possible between humans and nature, men and women, and different races and ethnicities. This global movement opens up a remarkable set of possibilities. In fact, they are so remarkable they threaten to overturn what for many is just the "natural order" of things. It should not surprise us therefore that across the world there has been a pronounced authoritarian backlash from social conservative and fundamentalist movements of all stripes.

Globally, it has led to the repeal of legislation designed to protect the environment, the rights of women and minorities, and is accompanied by a cut to close borders to prevent the entry of immigrants and a rise in xenophobia. Authoritarian leaders tap into the “cultural anxiety” that has emerged for some groups as a result of the silent revolution and its implications, who see that they will no longer be a dominant majority, that their values no longer reflect the nation’s, and consequently feel that this is not their country anymore (Jones et al. 2017).

But even beyond the cultural anxiety, there is what we might call an existential anxiety. *This period of transition, and specifically the silent revolution, poses challenges to the very way human beings understand what it means to be human, their nature, role, and possibilities at a fundamental level.* We will look at three interconnected crises and challenges highlighted by Inglehart and Norris. They are the crises of humanity vis à vis nature, gender, and race and ethnicity.

The implications of the silent revolution involve radical changes to arrangements that have been in place in some form or other for thousands of years. Many people regard these arrangements, such as “traditional” roles for men and women, as “natural” or God-given. As a result, any change for them is not just wrong but an attack on the natural order. Furthermore, while images of the old order are pervasive, *images of a “successful” outcome of the silent revolution are few and far between in the social imaginary.* Even for those who support the silent revolution, it is easier to critique the existing order than to articulate what the new order could be like. Futurist and philosopher Jay Ogilvy has pointed out the absence of scenarios of better futures (as opposed to utopian visions), and also emphasized the need to think about them and generate them in a different way, going beyond the optimism-pessimism clash to a more complex “tragi-comic” view that acknowledges the reality of suffering and the reasons for pessimism, while also retaining the optimism and belief in possibilities that will get one off the couch and allow for hope (Ogilvy 2011).

One key reason why the crisis is so pervasive is that it reflects a certain kind of thinking, a thinking that is reductive and disjunctive. This appears as an exclusive focus on analysis, on isolating variables, and quantification. Interestingly, this kind of thinking was never able to account for creativity. This kind of thinking cannot now envision convincing possibilities for the future because it is precisely the kind of thinking that led to both the successes and now the exhaustion of modernity. For our purposes, this is most notable in the way creativity was conceived and practiced in modernity, because *human creativity is what generates possibilities.*

When the silent revolution is placed in a historical/evolutionary context, it becomes clear that, with some notable exceptions, despite the enormous variety in global cultures, nature, gender, and race have all been marked by relationships of domination – humans over nature, men over women, and “us” versus “them” (Montuori and Conti 1993). The global values change is threatening a status quo that has been in existence for hundreds and even thousands of years. It is threatening core aspects of what is perceived to be human identity, and from within that frame of domination, either A dominates B, or B dominates A. As a result, the change is interpreted as a reversal loss for the dominant groups, so it should perhaps be no surprise then that there is a powerful backlash and extreme polarization. The possibility of mutually beneficial, or what Eisler calls “partnership” relationships, is not entertained as a possibility (Eisler 1987; Eisler and Fry 2019).

Beginning with the human relationship to nature, we see that in the past 2000 years, Judeo-Christian religions have historically preached “man’s” dominion over nature. Particularly since the Industrial Revolution, humanity has gained more and more control over nature. In the process, it has also separated itself from nature, with the result that a vast proportion of human beings in industrialized societies do not see themselves as interconnected and interdependent in their relationship with nature or each other. The current environmental crisis is to a large extent the result of this human dominion, particularly with industrialization. The response to this crisis has led to

the emergence of a powerful environmental movement and proponents of a holistic worldview – a worldview which more than echoes those held by Indigenous peoples all over the world (Capra and Luisi 2014; Wood 2012). The nature of the crisis is such that there have been arguments for drastic changes in consumption and in the economy, changes that would in many ways transform society. Along with this very clear and important economic dimensions, there is also a psychosocial, existential dimension.

At an existential level, the environmental crisis leads to fundamental questions about humanity's relation to nature. There has been a call for a transformation in the relationship between humans and nature. An "ecological self" is not like an individualistic atom, separate from nature, but interconnected and embedded in nature (Macy and Johnstone 2012; Mathews 1991). It is a movement away from an *anthropocentric* view, which holds that there is a clear dividing line between humanity and the rest of nature and establishes human superiority over the rest of the world. In this view, humanity is the principal source of value and meaning in the world, and nature exists for the benefit of humanity (Purser et al. 1995). *Ecocentric* views do not put human beings as the sole source of value and meaning and propose a number of variations on a more interconnected, interdependent self that does not view itself as dominating nature, but in a relationship of partnership (Eisler and Fry 2019). On an existential level, the environmental crisis is also pointing to a new sense of human identity, one that is not separate from Nature, but is more interconnected and interdependent. This view clashes dramatically with the "free market utopia" view that emphasizes the importance of the economy and of independent, unfettered individuals above all. But it should be noted that the full implications of ecocentric views have not been articulated in a modern industrial technological context or extensively applied. This is also the case for the possibilities of partnership relations, whether between humans and nature or men and women. This adds to the uncertainty of the current situation.

The reality of *interconnectedness* and *interdependence*, emphasized by environmentalists

as well as systems and complexity thinkers and Indigenous worldviews, has been made painfully obvious by the pandemic of 2020 (Cajete 2000; Capra and Luisi 2014; Morin 2008). In the United States, this view goes against the historically strong valuing of individualism and the conquest of Nature. Historically, movements such as Romanticism valued Nature in less instrumental ways, and Indigenous societies throughout the world had radically different views that are now being held up as models of harmony with Nature. The interest and appreciation for Indigenous cultures is also leading to a questioning of the alleged cultural superiority of the West, its cultures, and worldview(s). In other words, it is challenging the superiority of the West's identity, and thereby the identity of its people.

The environmental movement is asking human beings in industrialized nations to drastically rethink their relationship to the environment, as well as rethinking a profound aspect of their identity. The gradual shift away from industries that are associated with Industrial Age pollution such as mining show the interconnection between economics and identity and the interconnectedness of the transformation. Certain types of jobs are disappearing because of environmental trends and automation. The disappearance of these jobs also leads to the disappearance of certain kinds of identities – most notably traditionally male, working class jobs not requiring a college education.

The 3 crises are interrelated and turbocharged by current communication technology and the resulting compression of time and space. Vast numbers of traditional working-class jobs disappear because of automation and the green economy. Men without 4-year college degrees are particularly hard-hit. They have lost much of the sense of identity that their jobs provided them, while also seeing no hope for the future. A large number of white men resist so-called green behaviors because they view them as fundamentally "feminine." For them, green and feminine are cognitively linked (Brough et al. 2016). Avoidance of femininity has been found to be an American cultural norm for masculinity. Notions of interconnectedness and interdependence are closely identified with the environmental movement. They go against traditional views of

masculinity in the West, where the stress is more on self-assertion and independence, while being relational is associated with women (Eisler et al. 2016).

Along with the crisis of human identity vis à vis Nature, the second existential and interrelated challenge to traditional identity is gender. Once again, a very long-standing arrangement that dates back at least 2000 years, the subservience of women to men, is being challenged. During that time in the West, but arguably all across the world with some exceptions, men and women have had clearly defined roles and status. Gender identities were identified in opposition to each other. Being a man meant not thinking/feeling/doing like a woman, and vice versa (Eisler and Fry 2019). We saw an example of this oppositional identity in the American cultural value for men of avoidance of femininity. Other cultural norms for men include negativity toward sexual minorities, toughness, dominance, and restrictive emotionality, whereas female cultural norms include relational, put others first, and sweet and nice (Mahalik et al. 2003; Mahalik et al. 2005). To change this fundamental relationship strikes at the very heart of gender identity, of what it means to be a man and what it means to be a woman. The critique of binary views of gender and the increasing emergence of LGBTQ voices have created a range of alternatives that were previously mostly submerged and make gender identity a much more complex phenomenon.

Women are now increasingly becoming breadwinners in the home, going to university in greater numbers than men worldwide (Bilton 2018), as well as taking on roles that were previously reserved exclusively for men. At the same time, men and boys are experiencing a crisis. Roles traditionally associated with men are eroding. Men and boys are unclear about what it means to be a man. Many young men drift aimlessly, and older men are committing suicide, the biggest victims of America's "epidemic of despair" (Case and Deaton 2020; Hymowitz 2011; Rosin 2012; Zimbardo and Coulombe 2016).

A third crisis relates to race and ethnicity. As is the case with environmental and gender issues,

concerns about social justice, ethnic identity, racism, prejudice, and discrimination have become louder and more insistent. The backlash to the silent revolution has focused strongly on nationalism, on us versus them, and on maintaining the inferior status of minorities and those perceived as out-groups by the traditional majority. This has been the case in Europe as well as in the United States, which saw the racist backlash that followed the election of Barack Obama and the candidacy of Hillary Clinton. The symbolism of having the world's most powerful country led by a person of color joined by two women (Nancy Pelosi and Hillary Clinton) was a tipping point for people who rejected the possibilities opened up by the silent revolution.

The post-Obama backlash coincided with the rising numbers of immigrants seeking refuge from war-torn countries and the rejection of immigrants. Martin Luther King's vision was undoubtedly one of interconnectedness (King 1987; Wood 2012), and the silent revolution presents a more globally interconnected, global, cosmopolitan vision. Once again, this trend involves a shift in an arrangement that has been the case for thousands of years: the despicable tendency of one "race" to view itself as superior to others. All three of these crises are based on domination of one over another. And all of them can be used by political leaders to manipulate groups to support specific interests.

The environmental, gender, and race issues at the beginning of the twenty-first century reflect the possibilities of truly transformative changes. They represent a call for changes to relationships and identities that for thousands of years were viewed as "natural," as "just the way things are." "Man" has dominion over Nature, women, and "lesser" races, cultures, and ethnicities. These issues also challenge human possibilities: Can human beings understand themselves as interconnected and interdependent rather than either individualists or collectivists? Can human beings create relations of partnership rather than domination? More broadly, can human beings mobilize their creativity to create these new possibilities, these new ways of being in the world (Montuori and Conti 1993)?

Crisis of Complexity

The Crisis of the Future is also a Crisis of Complexity. It is commonplace to say the world is getting more and more complex. In this context, the word complex may mean a number of things, which usually include not being able to make sense of it. Undoubtedly, the compression of time and space and communication technologies have made a great difference in the last 20 years. As a result, the world is much more interconnected, interdependent, and uncertain, and changing much more rapidly so than ever before. Information can travel over the entire globe instantaneously, and people can do so in 24 h.

With the Internet, human beings have access to more information than ever before. If until the middle of the twentieth century the Encyclopedia Britannica was an acceptable reference point for knowledge, today there is an almost inconceivable proliferation of voices and perspectives, and it seems humans are quite unprepared to deal with this information overload. Information is also manipulated, with websites and bots spreading propaganda and disinformation. As a result, the new term “post-truth” refers to the absence of shared objective criteria for truth.

For Morin, there is something deeply problematic about the very way human beings in the West think, or more broadly, the way they make sense of the world. Morin’s key point here could be summarized by the apocryphal comment, attributed to Albert Einstein, that current problems cannot be solved with the same type of thinking that created them. Is it possible to think about futures and to create better futures with the same way of thinking that informed the modern age? For Morin, the answer is no. What is required is a different way of thinking. Morin refers to it as “complex thought.” While reductionism, disjunction, abstraction, and the quest for certainty have been extremely successful, this “strategy of simplification” has reached its limit. Its limitations have become more obvious in a “networked,” interconnected, interdependent uncertain world

where context and connections matter. Morin writes that

We need a kind of thinking that relinks that which is disjointed and compartmentalized, that respects diversity as it recognizes unity, and that tries to discern interdependencies. We need a radical thinking (which gets to the root of problems), a multi-dimensional thinking, and an organizational or systemic thinking. . . . (Morin and Kern 1999, p. 130)

An increasingly complex – interconnected, interdependent, uncertain, pluralistic world requires a way of thinking that can address this complexity.

The criticism of dominant ways of thinking in the West, and which found support in systems theory and cybernetics, has been that analysis breaks apart complex phenomena in order to understand them, but in the process gives a partial view only, not addressing interconnectedness and emergent properties. This is particularly apparent when addressing living systems. I would add that current problems cannot be solved with the same creativity that created them. What is needed is more complex, contextual creativity.

Complex can be contrasted with simple. As numerous thinkers have pointed out, the human identities we are referring to here, vis à vis Nature, Gender, and Race, are *oppositional identities*, meaning where men define themselves in opposition to women, whites in opposition to blacks, and humans in opposition to Nature (e.g., “he behaved like an animal”) (Wilden 1987). These oppositional identities are relatively “simple,” something most people would view as stereotyped, with clearly defined roles. They can be framed in terms of a simple either/or. One is either male or female, and one dominates the other. From that frame, the transmovement and notions of “fluid” identities are shocking, again, opening up unacceptable possibilities.

The fact that these identities, “human nature,” “gender,” and “race and ethnicity,” are changing means they are becoming more complex, and one example of the greater complexity is gendered identity. Instead of embracing one fixed pole of a

duality, there is a cybernetic relationship between, and transformation of, what were formerly the two choices of male and female. Such cultural norms as toughness for men and sweet and nice for women are traditional cultural ideals, and not just in America. They represent a polarization which drastically limits the full humanity of men and women by reducing what it is possible for a human being to be. Gender roles are, in this sense, a trap, a box. We can see this clearly in such norms as avoidance of femininity and restrictive emotionality (limited emotional range) for men, and relational, sweet and nice, thinness, and put others first for women. The breakdown of the oppositions leads to more complexity and a process of navigating between the range of possibilities. Barron's research showed that creative individuals do not conform to social gender stereotypes (Barron 1972), and beginning with Maslow's early research on self-actualizing, we see psychologically healthy as well as creative individuals embody the resolution of dichotomies that were normally viewed in an either-or frame (e.g., either tough *or* sensitive) (Csikszentmihalyi 1996; Kaufman 2020).

Creativity is the generator of possibilities itself. The creativity of modernity led to an incredible global transformation. But this creativity had certain characteristics which are now quite counterproductive. It was rooted in what Morin calls the paradigm of simplification, it was essentially atomistic, focusing on individuals (the lone genius) and industries at the expense of their context, their environment (Montuori and Purser 1995). It was compartmentalized (e.g., restricted to individual of "genius" and the arts and sciences), not taking account interdependencies or context. The image of the lone genius was very much associated with self-destructiveness, not just with "madness," but with abuse of the body (the "environment" of the "spirit") whether through drugs, drinking, or illness (McMahon 2012). Creativity in industry was decontextualized, and industrial pollution, for instance, was simply dumped into "the environment." The business of business was

business. The disjunctive thinking split humans and nature, and more generally any system from its environment. As a result, the environment was seen as something "other" to humans, and its condition had no implications for humans, with results that are now becoming all too obvious.

This individualistic, atomistic view of creativity is now increasingly being challenged in the creativity research literature (Glăveanu 2017; Glăveanu et al. *in press*; Montuori and Purser 1995). Alternative practices and philosophies, such as regenerative culture and biomimicry, are offering radically new approaches with very different views and relationships between any system and its environment (Benyus 2002; Wahl 2016). For the emerging generations that have grown up in a networked society, interconnectedness is just a fact of life. Generations that have grown up in an interconnected, networked society (Millennials, Generation Z) appear to see creativity differently than baby boomers, viewing it as a more relational, everyday process (Montuori 2011).

A feature of the emerging creativity, expanding on the principle of a more complex creativity (i.e., contextual, collaborative), is an explicit move beyond the realms of art and science, where it clearly resided in modernity, into the realms of *expanding human possibilities*. This includes what Maslow called "self-actualizing creativity," or creativity directed to the process of "self-creation," in order to develop a more complex sense of human identity (Maslow 1959). It also includes *creating* win-win interactions, striving to direct creativity toward making human interactions in an interconnected, interdependent world mutually beneficial, something that becomes an ethical imperative in a time of transition.

The crisis of the future is also a test of human possibilities, of what human beings are capable of. Can human beings learn to know and think in a way that does justice to the interconnectedness, interdependence, and uncertainty in the world? Can human beings learn to create mutually beneficial, win-win relationships? Can human beings

recognize their own creativity and the creativity of nature, and take responsibility for their creations?

Conclusion

The crisis of the future is the result of an interrelated poly-crisis in a time of transition as modernity is dying. Coupled with the effects of technological developments such as the Internet and automation, a movement of global value change, a silent revolution transforming humanity's relationship to nature, as well as gender and racial equality, has led to an authoritarian backlash. Because they touch on core aspects of our identity as human beings, our identity vis á vis nature, gender, and race/ethnicity, the threat posed by these changes has in turn led to great polarization.

The crisis of the future is also a crisis of complexity. The world is more interconnected, interdependent, uncertain, and pluralistic. In order to make sense of it, and in order to comprehend the complexity of emerging post-binary postoppositional identities, a different kind of thinking is needed, which Morin refers to as complex thought. In order to create new worlds, a complex creativity is necessary, one that recognizes human complexity and expands human possibilities, and in which creativity is directed toward the creation of mutual benefit. The crisis of the future is, finally, a test of human possibilities, a test of what human beings are capable of – how they think, create, relate, and act.

Curiosity

Ilhan Inan

Philosophy, Koç University, Istanbul, Turkey

Abstract

Research on curiosity in the sciences and in philosophy is still in its infancy as indicated by the fact that there are more controversies than there are commonly agreed positions on the topic. This chapter takes up some of the fundamental questions on curiosity and gives a summary of the different views researchers have adopted on these issues. These questions include what curiosity is, how it is aroused, whether it is an aversive state, if it requires awareness of ignorance, how it relates to asking a question, what satisfies it, in what way it is valuable, and whether it can be immoral. Based on these preliminaries, the chapter then discusses the various ways in which being curious relates to different modes of possibility.

Keywords

Curiosity · Wonder · Desire · Drive · Information · Knowledge · Ignorance · Awareness of Ignorance · Reference to the Unknown · Satisfaction · Questions · Asking · Answering · Real Possibility · Epistemic Possibility · Value · Virtue · Morality

What Is Curiosity?

Plato famously said that philosophy starts with *wonder* (thaumazein). The ancient concept of wonder has been associated with awe, amazement, and perplexity, but all of these are passive states that lack a motivational force. The only other component of wonder that has this feature is curiosity, which is the driving force that motivates us to inquire into the unknown and explore reality and our own existence in it. How to define curiosity, or even if it can at all be defined, however, has proved to be very difficult. One major reason for this is the dispute on whether

being curious is a special instance of a more general state. The common trend among philosophers is to take curiosity to be a form of desire. Aristotle's (1924) famous first statement of his *Metaphysics* (350 BC), "All humans, by nature, desire to know," gives us the most popular definition of curiosity (though Aristotle himself does not mention curiosity). David Hume (1986) defined it as "the love of truth," a strong desire which is the source of all our inquiries; Thomas Hobbes (1994) thought of curiosity as "a desire to know why and how" and held that, together with reason, it is what separates us from other animals; Rene Descartes (1989) held that desire is one of the six primitive passions of the soul and defined curiosity as "a desire to understand." Different versions of these desire accounts of curiosity have entered our modern dictionaries as a desire to learn, to inquire, to gain novel experiences, etc. Most psychologists, on the other hand, hold that curiosity is a drive. The pioneering figure in curiosity research, Daniel Berlyne (1954), takes curiosity to be a conflict drive, i.e., the state a being is in when their past experiences are in conflict with their new experiences. Harry Fowler (1965) defines curiosity as a boredom drive, that is, the state a being is in when they lack external stimuli, which exhibits itself in the form of exploratory behavior, motivated by sensation seeking and novelty seeking. One of the most influential figures in contemporary psychology on curiosity research, George Loewenstein (1994), sets this issue aside by arguing that the question of whether curiosity is a primitive drive is one that cannot be answered and is not that important and developed his information-gap theory. On this view, a being becomes curious when they become aware that there is a gap between what they know and what they wish to know. Within the more recent studies in neuroscience, the most common trend is to define curiosity as information seeking (Kidd and Hayden 2015), acknowledging that this is at best a working definition that is vague and perhaps too general. (For interdisciplinary work on curiosity see (Inan et al. 2018; Zurn and Shankar 2020)).

The two most popular accounts of curiosity, as *desire for knowledge* and as *information seeking*, have been challenged by a number of philosophers; Jonathan Kvanvig (2003) argues that animals and young children who do not possess the concept of *knowledge* can still be curious, from which he concludes that curiosity cannot be defined as a desire to know based on the assumption that one cannot desire something they cannot conceptually represent. If this argument is sound, it may also shed doubt on the view that curiosity is information seeking, given that animals and young children may also lack the concept of information. Another argument against both accounts involves cases in which one desires knowledge or seeks information, but yet is not curious (Inan 2012; Schmitt and Lahroodi 2008; Yiğit 2018). One's motivation to seek knowledge or information may be based on practical concerns and not involve an intrinsic interest in the topic, for instance, a student who wishes to acquire knowledge just enough to pass an exam on a topic that he or she has no interest in. On the other side of the coin, there may also be cases in which one acquires knowledge or information that they seek but yet remains curious, or even becomes more curious. The discovery of the existence of black holes, for instance, gave scientists a valuable new piece of information about the universe, which in turn made them more curious about the nature of black holes. Another consideration that may tell against the two accounts involves cases in which one is curious about something but desires not to know it: imagine a jealous husband who is curious about whether his wife is having an affair, but desires not to know it, fearing that the outcome may ruin their relationship (Inan 2012). This gives rise to the idea that curiosity is a primitive mental state that cannot be defined in terms of desires or other emotions.

Despite the lack of consensus on what curiosity is, all researchers seem to agree that normal adults who have mastered a language and have the ability to reflect on what they are ignorant of can become curious and express this in the form of a question which typically causes them to develop an epistemic desire to inquire into the unknown.

How Is Curiosity Aroused?

The common trend among researchers is to take typical cases of curiosity to be aroused by external stimuli. Seeing an unfamiliar object, hearing an unexpected sound, or being asked a novel question could make someone curious, and in such cases, the initial stimulus that arouses curiosity appears to come from the outside and thus may be said to be externally stimulated. This creates a tension for the drive theories of curiosity because primitive drives are typically considered to be internally stimulated: the feeling of hunger or thirst, for instance, is within the organism that motivates it to seek food and water. While on Berlyne's conflict account, unlike other basic drives, curiosity is typically aroused by external stimuli, the boredom account of Fowler takes curiosity to be internally motivated even when external stimuli plays an indirect role, because the feeling of being deprived of novel stimuli is what triggers the whole process initially. The more common approach is to take curiosity to be at times internally stimulated and other times to be externally stimulated (Loewenstein 1994). Such a mixed account could also be applied to cases in which curiosity is stimulated by the asking of a question. One may become curious as a result of hearing or reading a question asked by someone else, in which case curiosity may be taken to be externally stimulated, but one may also formulate a novel question in their mind and make themselves curious, and in such cases, it may well be said that curiosity is internally stimulated. The distinction thus has a bearing on how curiosity relates to creativity; while externally stimulated curiosity does not appear to involve a creative act, cases of internally stimulated curiosity that involve posing a novel question are considered to be a very special case of creativity (Inan 2015).

Is Curiosity Always an Aversive State?

Though there are some fundamental differences, most psychological theories perceive curiosity to be an aversive state, i.e., a negative state a being is in when they are deprived of information,

knowledge, or experience. On this account, being curious is not a pleasurable state, and only its satisfaction is. For this reason, voluntary exposure to curiosity has been associated with risk-taking (Loewenstein 1994). The idea that curiosity is always aversive has been challenged by some philosophers and very recently by some psychologists as well. David Hume (1739) thought of curiosity as a tool by which we fix our attention on our inquiries which at times could be pleasurable. Schmitt and Lahroodi (2008) remarked that curiosity may have intrinsic value in that it may give us pleasure, for instance, when we try to solve a puzzle for joy. Neuroscientific studies indicate that curiosity may be aversive (Jepma et al. 2012) but also at times pleasurable (Kang et al. 2009).

Does Curiosity Require Awareness of Ignorance?

There are important differences between drive-based accounts of curiosity and desire-based ones. Drives are considered to be primitive biological dispositions that need not involve the use of higher-order cognitive faculties, whereas desires in general are considered to be representational mental states. An animal who seeks nutrition, motivated by its hunger drive, does not have to represent in its mind the food it seeks. Similarly if curiosity is motivated by such a primitive drive, it should follow then that the curious being need not have to represent in their mind whatever it is that they seek, be it knowledge, information, or experience. This has led Berlyne to distinguish between two types of curiosity, perceptual and epistemic, where the former is the more primitive kind enjoyed by animals and pre-language children that is aroused by external stimuli coming from an object that is unfamiliar to the curious being. On this account, perceptual curiosity does not require awareness of ignorance. Epistemic curiosity on the other hand can always be put in terms of a question whose answer the curious being wishes to learn and thus requires the agent to come to realize that there is something unknown to them. On Loewenstein's

information-gap theory, all cases of curiosity, whether it is aroused by internal or external stimuli, require the agent to become aware of a certain gap in their knowledge, from which it follows that awareness of ignorance is always a precondition for being curious. Inan (2016, 2020) has argued that in order for a being to become aware of their own ignorance, they need to possess the meta-cognitive skill to mentally represent something as being unknown to them. These accounts have the implication that curiosity is a meta-representational state that may be absent in animals and young children.

How Does Being Curious Relate to Asking a Question?

While Berlyne held that only its more advanced form, that is, epistemic curiosity, requires the asking of a question, Whitcomb (2010), Loewenstein (1994), and Inan (2012) take all instances of curiosity to involve the asking of a question. Both Whitcomb and Inan have argued that the state of curiosity has conceptual content that can always be identified with a question. On the intentional-intensional model developed by Inan (2018), being curious always involves representing an unknown in the mind, which for normal adults who have mastered a language requires the formulation or the grasping of an inostensible concept, i.e., a concept whose object (referent) is represented as being unknown. Identifying the content of the mental state of curiosity with a question allows us to apply the various taxonomies made by philosophers and linguists on the different types of questions to the different types of curiosity. On the most standard distinction, there are the so-called *wh*-questions posed by interrogatives that employ question words such as *who*, *why*, *how*, *which*, *when*, and *where* that ask for an unknown person, a cause, a reason, a time or a duration, a place or a location, etc., giving rise to objectual curiosity, and then, there are the so-called *whether* questions that ask for whether a certain proposition is true or false giving rise to propositional curiosity (Inan 2012, 2014).

In a social context, the asking of a question out of curiosity is a speech act that involves the person asking the question and the one(s) expected to provide an answer. Being curious about something however does not always motivate the asking of a question to others. One can consult a book, an encyclopedia, or a website to find the answer to their question. There are also times when there is no person or text to seek an answer, for instance, when nobody knows the answer to the question. This suggests that there ought to be an extended use of the notion of asking a question, in which the curious person asks a question to herself or himself. This is not a speech act, but a mental act that takes place in the mind of the person (Inan 2012). When one is curious about whether there is intelligent life on other planets and knows that nobody knows the answer, there is a good sense in which they are asking the question to themselves as a private mental act.

What Satisfies Curiosity?

Another controversy concerns the question of what satisfies curiosity; on Loewenstein's information-gap theory, curiosity is sated when the agent acquires the missing information that they seek (though he also uses *knowledge* in place of *information* as well). In a similar vein, Kvanvig (2003) holds that the goal of curiosity is to attain what he calls "perceived truth," from which it follows that novel information that is perceived to be true by the agent is what sates their curiosity. A concern regarding both positions is that information that is attained as a result of being curious need not always be true and, even if true, may not be coming from a reliable source. This raises a further question about whether the satisfaction of curiosity is merely an internal subjective feeling or whether it has externalist conditions. When one asks a question out of curiosity and gets an answer that they believe to be true, their curiosity may end, but the question remains as to whether they have actually satisfied their curiosity, especially if the answer turns out not to be correct. Arguing against the subjectivist account, Whitcomb (2010) holds

that knowledge, and only knowledge, is what satisfies curiosity. Philosophers in general hold that in order for a piece of information that a subject believes to be true to count as knowledge, it must be true (since knowledge cannot be false), and further, the subject must have sufficient evidence or be justified in holding that belief. An intermediary position held by Inan (2012) argues for a mixed account, by distinguishing between a subjective and actual sense of satisfaction. On this view, curiosity may be subjectively satisfied even when it is not actually satisfied. There is then the further question of whether knowledge always satisfies curiosity: Can one remain curious about something they already know? Kvanvig (2003), Schmitt and Lahroodi (2008), and Inan (2012) give various examples of cases in which this could take place. Distinguishing between propositional and objectual curiosity, Inan (2014) argues that propositional knowledge that contains uncertainty and knowledge of an object that is partial leave room for curiosity.

What Is the Value of Curiosity?

There are two different but interrelated ways in which curiosity is said to be valuable. One is the value of a subject's being curious about a particular unknown on a specific occasion, usually identified as state curiosity; the other is the value of being a curious subject in general, in the sense of possessing a certain character trait, generally referred to as trait curiosity. These are dependent values; if it is good to be a curious person in general, this must be because it is good for that person to be curious about certain things in specific contexts. The debate concerning the value of trait curiosity recently emerged in a relatively new field called *virtue epistemology*, a field in which ethics interacts with theory of knowledge. It is inspired by Aristotle's virtue ethics. Aristotle held that a virtue is an excellence in character that one needs to have in order to lead a good life and argued that there are two kinds of virtues: moral virtues, which are those character traits that one ought to possess to be a moral person, and the

other is intellectual virtues (more commonly called "epistemic virtues") which are the character traits required to be a good knower in order to reach wisdom. Nowhere did Aristotle mention curiosity as being an epistemic virtue; contemporary virtue epistemologists have come up with lists of epistemic virtues which usually include traits such as inquisitiveness and open-mindedness, but only a few of them explicitly include curiosity on their list. Miscevic (2016, 2020) argues that curiosity is the basic virtue, underlying all other epistemic virtues, that motivates inquisitiveness in the road to reach truth and knowledge; Schmitt and Lahroodi (2008) hold that curiosity has instrumental value in that it is an original epistemic desire for knowledge that is not for the sake of any practical gains. This raises the question of whether curiosity has merely instrumental value or whether it could at times be intrinsically valuable as well. To test our intuitions on this, Inan (2012) developed a thought experiment, the Utopia Paradox; if knowing is what is intrinsically valuable, then the perfect world would be a place in which we know everything leaving no room for curiosity. If one has the intuition that such a world would not be a pleasant one to live in, leading to boredom, then we may conclude that curiosity also has intrinsic value. Expanding on this idea, Yiğit (2018) holds that the value of being curious and the value of acquiring knowledge (in order to reach understanding of reality) form an "organic unity," that is, the value of the whole exceeds the sum of the values of the parts. Apart from motivating inquiry, Hume (1986) has argued that curiosity has value in that it is an attention fixer, that is, when one is curious they fix their attention on the object of curiosity (the unknown entity); Schmitt and Lahroodi (2008) go even further and argue that the acquired knowledge motivated by curiosity increases the attention of the subject. More recent studies in psychology have confirmed that curiosity is not only an attention fixer, but as a result of this, it enhances and strengthens memory (Kang et al. 2009), indicating that knowledge acquired by curiosity remains in the memory for a longer span of time and is more easily retrieved.

There are various questions concerning the value of curiosity that require further studies. These include what role curiosity plays in inventions and discoveries; whether it is a prerequisite for creativity; how it could motivate us to become aware of our own ignorance and to ask novel questions; the way in which it could increase the depth and breadth of our knowledge; how it could be a remedy for boredom and our fight against dogmatism; how it relates to open-mindedness; what role it plays in our appreciation of the capacity of human intelligence; how it could extend the subject matters we are interested in, whether it is essential for healthy human communication, friendship, and love; ways in which it motivates self-knowledge and self-realization; how it relates to moral and practical deliberation and the exercise of freedom of the will; and how it could provide intellectual change in the right direction.

Can Curiosity Be Immoral?

Medieval philosophers thought of curiosity for the most part to be a sin, so much so that Augustine (401 AD) famously remarked that it is one of the primary sources of human evil. They identified three different ways in which curiosity may be improper; the first concerns *what* one is curious about (i.e., directed toward the wrong piece of knowledge), the second concerns *why* one is curious (i.e., having the wrong kind of motive), and the third concerns *how* one becomes curious or tries to satisfy their curiosity (i.e., employing the wrong method) (Dunnington 2018). Examples of the first kind include being curious about unknowable things, trivial matters, issues that distract one from their duties, and concerns that are debasing or not edifying; curiosity based on an improper motive involves cases in which one seeks knowledge for pride or to use it for evil purposes or that distracts their attention from God; the third category of improper curiosity that employs the wrong method includes cases in which it is haphazard and not organized or appeals to forbidden sources. From a modern perspective, some of these cases are no longer considered to be improper or

immoral by many, especially from a secular point of view.

One should approach all these arguments with some caution for two reasons. One is that there is an important distinction between being curious on the one hand and acting upon your curiosity on the other. For instance, being curious about others is typically considered to be immoral when it involves infringement of privacy, but for that to be the case, it seems that the curious person should have acted upon their curiosity. It may thus be that what is immoral is the performed action and not the mental state of curiosity. The second issue concerns the issue of whether being curious is voluntary. When one becomes curious as a result of internal or external stimuli, it may be that this is not something they intentionally choose to do with their free will. If curiosity is a mental state that emerges involuntarily, as is the case for most of our beliefs and desires, then being curious as a mental state cannot be the object of moral judgment. As the famous slogan goes, *ought implies can*, that is, one can only be praised or blamed for acts that they can do or avoid to do. In many of these cases of improper curiosity, it may be that what is immoral is not the state of curiosity per se, but one's actions that are motivated by it which in normal circumstances are considered to be voluntary acts.

How Does Curiosity Relate to What Is Possible?

Humans have the capacity to think of not only what is actual but also what is possible. The ability to represent possibilities underlies our aptitude for curiosity. In order to be curious about whether there is life on other planets, one must be able to represent in their minds two incompatible possibilities, only one of which is actual. For such empirical matters, the mode of possibility that we appeal to may be said to be real possibility, assuming that it is physically possible for there to be life or no life on other planets. But human curiosity is not limited to this mode of possibility. One can be curious about whether an unproven mathematical hypothesis, such as Goldbach's

conjecture, is true or false, and in such a case, not each option has real possibility, given that if the hypothesis is true, then it being false is not mathematically or even logically possible. Here, the mode of possibility is epistemic in that both the possibility of the hypothesis being true and being false are epistemically open to the agent since they do not know which is correct.

There are other ways in which curiosity relates to what is possible as well as what is impossible. First involves the issue of the limits of curiosity: what a person can be curious about is essentially determined by what is possible for them to ask (Inan 2012). Given the recursive and compositional structure of a natural language, there are infinitely many possible questions that can be formulated by using its finite vocabulary of words. A speaker of a language knows some of those words, but not all, and every known word corresponds to a concept in their mind. These known words constitute a part of the idiolect of that person; the richer it is, the more questions they can ask. In other words, the number of inostensible concepts that they can grasp is determined by the concepts of their idiolect. A person who has the concepts of *the solar system*, *planet*, *moon*, *number*, and *most* may bring them together by utilizing rules of syntax to formulate the question “which planet in the solar system has the most number of moons?” and then by an act of epistemic self-reflection, they may come to realize that they do not know the answer, and if they have an interest in the topic, this may arouse their curiosity. A member of a community that has a primitive language that does not contain such concepts cannot construct such a question and thus cannot become curious about this, nor can a child that has started speaking a language but has not acquired all these concepts yet.

Another way in which curiosity relates to the possible concerns not the questions they can ask, but the possible answers they can conceptualize of a particular question that they can ask. The person who is curious about which planet in the solar system has the most number of moons may narrow the range of the possible answers to their question to, say, two options: it is either Jupiter or Saturn. These are two possible answers, and

only one of them is correct. The ability to conceptualize possible answers to a question asked out of curiosity is what allows a being to formulate hypotheses which in turn may arouse further curiosities that motivate further inquiries. Note that being curious which planet has the most number of moons in the solar system is different from being curious as to whether Saturn is that planet. This is one way in which curiosity can be tenacious; that is, a question asked out of curiosity may give rise to further questions as long as it is possible for the curious person to formulate hypotheses that are the possible answers to the original question. Before the discovery of Saturn, though it may have been possible for people to be curious about which planet has the most number of moons, it was not possible for them to be curious about whether Saturn is that planet, given that they did not have the means to refer to it in their idiolect.

Curiosity interacts not only with what is possible in these ways but also with what is impossible as well. One way in which this happens is when one asks an answerable question that leads to insatiable curiosity. This is the case when one has the means to conceptualize an unknown through the asking of a question, but it is impossible to know the answer, either for the subject herself or for all humans. Medieval thinkers thought of such instances of curiosity as being improper and even as a sin, arguing that one ought not seek knowledge that is beyond their reach. What tells against this is that in order to determine that a question is unanswerable, one should first ask that question, so it seems that being curious about what turns out to be unknowable is a good way in which one discovers that that aspect of reality is unknowable. Curiosity about some future state of the world may be such a case. It may turn out that some events are not governed by deterministic laws, which makes the future open; on such a view, there are various possible futures compatible with the state of the world now, and there is simply no fact of the matter as to which one of those possibilities will turn out to be an actual state of the world in the future. This may be the case if there is some indeterminacy at the quantum level or if humans have a free will

that is incompatible with determinism. In an indeterministic world as such, it is impossible to answer some questions about the future, though some of these questions arose the curiosity of many.

Another way in which a question is unanswerable in a more qualified sense is when the question is based on a mistaken presupposition. Before Euclid gave his elegant proof that there are infinitely many primes, it must have been natural for mathematicians to be curious about what the largest prime number is. It was well known then that the frequency of prime numbers in a given range decreases as the numbers go up. The question “what is the largest prime number?” presupposes that such a number exists, and in this sense, the question cannot be answered, at least not in the ordinary way. If one does not know that the presupposition of a question is mistaken, one can still be curious about it. And this is definitely not a waste of time, nor is it improper, or a sin, for such instances of curiosity allow us to discover that the question is unanswerable which indicates progress in our knowledge (Inan 2012).

The way in which being curious relates to the conceptualization of what is possible may also manifest itself in certain forms of creativity (see also “► Inspiration”). A designer, an inventor, or an artist typically conceptualizes the entity they wish to create, which is initially merely possible and not actual. If a case can be made that the creator may in fact be curious about the end product they wish to create (Inan 2015), then it should follow that this very special form of curiosity requires the conceptualization of the possible.

Abstract

Daydreaming can be defined as the process by which we partly or fully decouple from what seems to be one's current activity in the world. It usually designates "anything one may be thinking about that does not pertain to the task in which one is currently involved" (Pereira and Diriwächter, 2008). Occurring within our flow of consciousness, it entails fantasy or a form of diurnal dreaming. Daydreaming can be more or less deliberate, have more or less clear goals, be more or less structured, and have diverse types of outcomes. Authors usually distinguish daydreams that may enrich people's relation to themselves, or their relation to the world, from those which seem not to enrich experiences. Most authors admit that daydreaming participates to our capacity to deal with our experiences and opens up new possibilities.

Introduction

Daydreaming has long been identified as a form of dream with open eyes, a way of being lost in fancy. In common sense as well as in psychology, daydreaming can be seen more or less positively: either as a very positive and constructive process, as a form of harmless distraction, or as loss of time or even a negative process. It follows that daydreaming can be seen as more or less connected to the possible: daydreaming can be seen as a process that leads to the creation of new possibilities in life, or on the contrary, as something that prevents or impedes our engagement to the possible. Interestingly, these positions partake to different psychological traditions: psychoanalysis on the one hand, and on the other, more conventional psychology, connected by the pivotal work of Jerome L. Singer. This text has two main parts. In the first part, we review studies on daydreaming by highlighting their relation to the possible. We thus distinguish authors for whom daydreaming is a usual activity of mind

which is enabling the possible; others who believe that daydreaming can even expand the possible; authors for whom daydreaming constrains the possible; and authors working with a non-processual model of mind for whom daydreaming is an obstacle of the possible. In a second part, we build on this work and first adopt an analytical stance to distinguish content, form, and function of daydreaming; we finally define a sociocultural approach to daydreaming, according to which daydreaming is a semiotic process building on past internalized experiences, reconfigured in new ways, thus expanding the possible.

Reviewing Daydreaming

Daydreaming as Enabling the Possible in Psychoanalysis

Psychoanalysis is focused on psychological processes by which “the obscure ways of [the] unconscious” can be made clear (Roudinesco and Plon 2007, p. 822). Psychoanalysis is a theory that assumes our lives are marked by the work of unconscious processes and highlights their affective nature; in addition it is an approach that assumes that semiotic processes – through language or other signs – can give form to our experience. In that domain, the notion of daydreaming is closely linked to those of fantasy, phantasy, dreaming, mind-wandering, and imagination (Laplanche and Pontalis 2007). For Freud, the creator of psychoanalysis, daydreams or phantasies are made of some traces of experiences, now combined in new ways:

Phantasies arise from an unconscious combination, in accordance with certain trends, of things experienced and heard. (...) Phantasies are constructed by a process of amalgamation and distortion analogous to the decomposition of a chemical body, which is compounded with another one. For the first sort of distortion consists in a falsification of memory by a process of fragmentation in which chronological relations in particular are neglected. (...) A fragment of the visual scene is then joined up with a fragment of the auditory one and made up into the phantasy, while the fragment left over is linked up with something else. In this way it is made impossible to trace up an earlier connection. (Freud 1966, p. 252)

Other authors, such as Winnicott, Lacan, and Klein agree upon the experiential component in defining daydream’s content. There are bits of previous experience that are recomposed and constitute the feelings and scenarios delineated by daydreaming.

Freud also considered daydream as a natural and usual process, in which we are daily engaged. It is a spontaneous activity, as is children’s playing, and it is actually a continuation of children’s play:

As people grow up, then, they cease to play, and they seem to give up the yield of pleasure which they gained from playing. But whoever understands the human mind knows that hardly anything is harder for a man than to give up a pleasure which he has once experienced. Actually, we can never give anything up; we only exchange one thing for another. What appears to be a renunciation is really the formation of a substitute or surrogate. In the same way, the growing child, when he stops playing, gives up nothing but the link with real objects; instead of playing, he now phantasies. He builds castles in the air and creates what are called day-dreams. I believe that most people construct phantasies at times in their lives. This is a fact which has long been overlooked and whose importance has therefore not been sufficiently appreciated. (Freud 1959, p. 422)

Daydreaming is thus a common and usual process. It is often not taken very seriously, unless it is undertaken by artists, who cultivate their daydreaming capacity and who, thanks to their technique and talent, turn them into new and sharable cultural forms.

Most psychoanalytical traditions that developed after Freud admit with him that daydreaming is a key activity of our mind. Daydreaming participates to the processes by which mind elaborates or integrates more or less affectively charged experiences, and makes them acceptable or meaningful for the person. Daydream transforms experience by the process of decomposition of traces of past experience (personal, but also cultural, relational, etc.) and their reorganization in new psychological experiences. The processes by which these recompositions occur are those described by Freud in his analysis of dreaming and include displacement (of affects and content from semiotic forms), figuration (of abstract ideas

into concrete things), and crystallization (of complex webs of meaning and affects into specific patterns) (Freud 2001a, b). Daydreaming can take many forms, which are more or less conscious and more or less deliberate; their affective tonality can be positive or negative. This has been further explored by authors after Freud. Lacan shows that fantasies can have a defensive function and are the byproduct of a frustration of some form of satisfaction in daily life. They hence represent some psychic activity, they can be reflected upon, and they can thus give rise to new form of activity (Lacan 1982; Roudinesco and Plon 2007, p. 287). Piera Aulagnier, who followed some of Lacan's work, considered fantasy as the result of primary processes and thus as the product of a pursuit of pleasure (Castoriadis-Aulagnier 1975, p. 26). These authors agree upon the function of daydreaming: it thus constitutes a form of elaboration or transformation of affects, be they pleasurable, paradoxical, or unpleasant.

For psychoanalytically inclined authors, such as Freud, Winnicott, Lacan, and many others, daydreams can thus either simply accompany one's flow of thought or activities, and be free floating and associative, or can take the shape of systematic and deliberated scenario. These can be negative, as when some anxiety accompanies a travel to a new place, or positive, as when we anticipate with excitement what will be. Yet, the paradoxical and ambivalent nature of human experience – the fact that we can very strongly desire certain things and yet loath their very thought at the same time – dissolves some of the boundaries of this taxonomic classification.

Altogether, daydreaming is thus more generally seen as oriented toward the possible: some daydreams are oriented toward the future and thus preparing it; most daydreams engage, to different degree, the elaboration and therefore transformation of experience, which could be otherwise preventing activity; it thus enables the person to welcome what is to come and engage in new experiences.

Within that tradition, only few authors, such as Winnicott or Tisseron, consider that some forms of daydreaming are not linked to the generation of the possible those that engage a compulsive,

dissociated, and defensive semiotic process. They are not related to the person's affects or in relation to the world:

The patient may sit in her room and while doing nothing at all except breathe she has (in her fantasy) painted a picture, or she has done an interesting piece of work in her job, or she has been in a country walk; but from the observer's point of view, nothing has happened. In fact, nothing is happening because of the fact that in this dissociated state so much is happening. On the other hand, she may be sitting in her room thinking of tomorrow's job and making plans, or thinking about her holiday, and this may be an imaginative exploration of the world and of the place where dream and life are the same thing. (Winnicott 2001, p. 27)

Similarly, Tisseron considers that we can enter in a form of empty fantasy activity – empty in the sense that it does not participate in semiotic elaboration, for instance, as when we play repetitive online game without emotional participation (Tisseron 2012). In these examples, the authors distinguish two functions of daydreaming: that of the elaboration of experience and another compulsive, dissociative, yet defensive, which would not appear to participate in making life in the world possible for that person.

Daydreaming as Expanding the Possible: Jerome Singer's Legacy

In psychology, the first systematic exploration of daydreaming was made by Jerome L. Singer, who in 1975, dedicated a whole monograph to the topic which became foundational for the study of daydreaming. The book, reedited in 2014, opened with a phenomenological exploration of the author's own daydream, which consisted of a complex scenario, built over the years as self-standing world, and that he could summon at will (Singer 2014, Chapter 1). Trained as psychotherapist and working as experimental psychologist, he later developed systematic studies of daydreaming, including collecting testimonies in the media and the arts, observation, introspection, projective tests, questionnaires, and scales. Vast cohorts of college students in the 50s completed his questionnaires, including open questions and scales based for some part on theories of personality then in fashion. Most people did report

daydreaming, mainly visuals, and often before falling asleep. Regarding content, Singer writes:

we see that most people's daydream consist of projections in the future of the fairly practical immediate concerns they have in their daily life. This daydreaming cannot be equated with specifically wish-fulfilment ideation. It appears more appropriate to look upon the content for most of our sample as reflecting attempts at exploring the future. It is a form, of "trial action" in which individuals review a variety of alternatives, not by any means always involving satisfactory outcomes for themselves. (Singer 2014, p. 55)

Along the lines of psychoanalytic authors, Singer considers the remainder of daily life experiences as making up the content of daydreams. In terms of its function, he assumes a Jamesian position, which suggests that daydreaming is always part of our stream of consciousness and part of our handling the extreme complexity of the world in which we live. Experimental testing suggests that the less we are exposed to, or focused on, external stimuli, the more we can be attentive to our daydreaming. In other words, daydream is a regular feature of our waking life; we simply do not pay enough attention to it.

Through Singer and his colleagues' studies, contents of daydreams appeared to be about people, relations, daily incidents, food, sport, sex, travels, and mostly part of daily life concerns. Singer and colleagues also looked for age and sociodemographic variables explaining variations in daydreaming and, through scales evaluated by people, for clusters of daydreaming through statistical analysis. In terms of its affective nature, Singer indeed identified:

1. "Anxious distractibility in daydreaming": floating and worrisome daydreaming "is not a useful resource and [the persons] take little pleasure in it" (Singer 2014, p. 68).
2. "Guilty, negatively toned emotional daydream": these are the daydreams of people with high aspiration and self-doubts and ethical standards.
3. "Positive vivid daydreaming": this is "characterised by an enjoyment of daydreaming and its anticipation of the future and for self-distraction without any pathological implications" (Singer 2014, p. 70).

For Singer, it is then possible to identify two types of acceptance of inner life, one as more flexible, nonconforming, and interested in people, and the other as a form of curiosity toward the natural and physical world.

Finally, regarding the function of daydreaming, after reviewing the explanations available at his time, mainly psychoanalysis and cognitive approaches, Singer had a very modulated view: for him, the attention we give to daydreams and the way we handle our lives result from complex arrangements – biographical, educational, relational, experiential, etc. – and so daydreaming can have very different functions. Minimally, it is a way to enrich our experience: some are wishful explorations, some divert us from anger and frustrations, some provide us with distractions from boredom, and in many cases they are "rehearsals for future actions. They may suggest new and alternative ways of dealing with situations (. . .). They can encourage us to try new kinds of experiences, or at least to look for ways of reaching some compromise approach to these wishes" (Singer 2014, pp. 118–119). And indeed, for Singer, daydreaming is developed over the life span and could be supported through psychotherapy to enrich people's lives.

By all accounts, then, Jerome Singer's approach to daydreaming was open and generous; for him, daydreaming is a vital part of our experience, on the fringe of our consciousness, and plays a key function in enlarging possibilities in our lives, exploring them, testing them, or simply playing with them, so as to move on. Daydreaming is deeply related to the possible. In his own work, Singer moved to study of the development play and imagination, even into electronic age (Singer and Singer 1992, 2005, 2013).

Authors referring to Singer often work with his typology of daydreams and correlate positive vs. negative daydreams with different other variables or psychological functions. For instance, authors have found positive correlations between dysphonic daydreaming and sleep disturbance (Starker and Hasenfeld 1976) and negative correlations between positive daydreaming and sleep disturbances. Others, such as Morley (Morley

1998), propose a phenomenological approach to daydreaming, which critically addresses Singer's emphasis on content and, using the metaphor of daydream as theatre, distinguishes daydream as lack versus as fulfilment. However, it seems that such approach transforms a model focused on processes (daydreaming as understood by Singer, inspired by psychoanalysis) into a model of types (of positive vs. negative daydreaming, wish fulfilment vs. lack); thus theorized, daydreaming loses its relation to the possible, as we will now see.

Daydreaming as Constraining the Possible: Unconscious Phantasms and Private Theatre

Some approaches in psychoanalysis and psychology assume that the deeper structures or processes of the psyche can constrain the richness or form that a given person's daydream can take.

On the psychoanalytical side, many authors distinguish the possibly conscious or quasi-conscious nature of some of our fantasies, which are accessible to introspection and language, from other, deeper unconscious phantasies or phantasms. Grounding such distinction, Melanie Klein, a psychoanalyst who developed her understanding on the basis of the observation of very young infants, considers that daydreams find their form in deep and unconscious phantasies (Klein 1936). Because of their organizational force, these phantasies constrain the daydreams a person can engage in.

In a similar vein, Lacan distinguishes the imaginary concept of fantasy from that of phantasm (Lacan 1957). This notion conveys the idea that there is a form of dramatization of everyday life; the form that this drama may adopt for each person is depending on their phantasm (Lacan 1982; Roudinesco and Plon 2007, p. 287). In a slightly different manner, phenomenological approaches find a form of universal grounding in daydreaming; Morley thus proposes that daydreaming "reveals the meaning of moods and emotions as dramatic scenarios in a manner reminiscent of the Greek work theatron" (Morley 1998, p. 132). There is here a parallel between staging and daydreaming in Morley and the dramatic aspect of daydreaming developed by Freud, Klein, and Lacan, among others (Roudinesco and Plon 2007). Such approaches theorize the limits of

daydreaming or the potential constraining that it may entail. They acknowledge, in a more or less rigid way, that the grounding of psyche establishes some form of fluid boundary for otherwise potentially infinite combinations.

Daydreaming as Impossibility

The most recent research on daydreaming has taken the label of mind-wandering, and it may or may not refer to Singer's proposition. In this psychology, the focus is not on processes of thinking but rather on outcomes. Affects are not theorized much, yet are assessed (as "satisfaction" or "well-being"); meaning or semiosis is not seen as relevant. These are considered in link to activities positively evaluated by the researcher – mainly, work (or learning). For most of this literature, daydream is seen as nuisance to the valued activity (i.e., work): mind-wandering is a way to be off-task and is usually considered as a loss of time. For instance, in a paper provocatively called "a wandering mind is an unhappy mind," Killingsworth and Gilbert (2010) analyzed information obtained through a phone-based application about 2500 US person's activities, state of mind, and mood. Their results showed that mind-wandering occurs in 46.9% of the cases; they then add that although people

were more likely to wander to pleasant topics (42.5% of samples) than to unpleasant topics (26.5% of samples), or neutral topics (31% of samples), people were no happier when thinking about pleasant topics than about their current activity ($b = -0.52$, not significant) and were considerably unhappier when thinking about neutral topics ($b = -7.2$, $P < 0.001$) or unpleasant topics ($b = -23.9$, $P < 0.001$) than about their current activity. (Killingsworth and Gilbert 2010, p. 932)

This type of research, content-free and decontextualized, is however hard to interpret. In any case, for these authors, mind-wandering consists in a loss of cognitive resources which would be better invested in something more efficient; it is thus seen as the result of a "cognitive control failure" (McMillan et al. 2013 for a review). The very fact of not being able to control their thoughts would be what makes people unhappy (Stawarczyk et al. 2012). For such tradition, daydream harms or damages activities in which people should be fully involved; it is assessed

negatively and seen as limiting the possible – a possible achieved through goal-oriented work.

Of course, one could question whether daydreaming and mind-wandering really entail the same phenomena. Newby-Clark and Thavendran (2018) suggest, in their review of the literature, that the lack of definition of these terms has also obscured the fact that they usually are operationalized in different ways. They propose to define daydreaming as “imagining events.” This enables them to consider mind-wandering as a different phenomenon: it is just “off task” and passing from thought to thought, while daydreaming would thus be intentional and have an explicit object (i.e., imagining an event) (Newby-Clark and Thavendran 2018). This, again, creates a normative division within variation of daydreaming (goal orientation is good, off-task is bad) and loses the complexity and variation of daydreaming described by psychoanalysts and by Singer.

Expanding Daydream

Analyzing Daydreaming

After this review of approaches, we now propose to decompose their claims into four questions: (i) What is daydreaming made of, which refers to its content; (ii) what forms it can adopt; (iii) what shapes these forms; and (iv) what its function is.

What is daydreaming made of? Most authors agree on the fact that dreaming draws upon past experiences, which in mind, can be recombined in novel forms.

What forms can it adopt? There is much less consensus about the form of daydream. For the most comprehensive understandings, such as Singer's, daydreaming can take forms ranging from a general feeling to a fully formed scenario. A diffuse feeling of comfort may accompany the experience of suddenly hearing a long-lost song; that daydream may have no specific content, simply reenacting the feeling of safety that accompanied us the first time in which we heard that song. It can also take the form of a fully formed scenario; Singer thus described his former daydreams consisting of a whole season of football matches (Singer 2014); or one may engage in

such daydream meeting an old lover by chance in an airport.

What shapes these forms? The form of daydream can be shaped by different forces and material. First, daydream may be partly shaped by the actual conditions of daydreaming; the football match may arise while watching one's son play football, or the hours of boredom due to a missed flight may trigger the romantic daydream. Second, for psychoanalysts, these daydreams are shaped by deeper psychic organization or phantasm. Third, people's daydreams are not only made by the content of their past experience, these also shape the form of these contents. Classical studies suggest that people daydream different shapes when looking at clouds, depending on their socio-cultural experiences (Bartlett 1916, 1928); similarly, the material arrangement in which people move and live their lives produce patterns that can also shape daydreaming (Valsiner 2019).

What are the functions of daydreaming? As we have seen, the literature considers functions either in terms of outcome or in terms of process. In terms of outcome, daydreaming can be seen as constructive or dysphoric, positive or negative, and useful or useless. There is thus a difficult opposition between positive and negative affective qualities, not accounting for the paradoxical or contradictory nature of many of our desires and thoughts. In terms of process, daydream can be seen as elaboration of experience, which includes both the elaboration of affect through semiotic processes, and the production of novel forms based on such semiotic elaboration (i.e., have a new unexpected daydream). The process can have various degrees of relation to external stimuli – complete decoupling and intermediate or accompanied decoupling. We can then elaborate the past, for instance, going over a disagreement we had with a friend, reproducing what we replied and exploring alternative ways in which we could have engaged. This may give us the pleasure that that situation didn't have or simply calm us by making sense of what happened. In the present, daydreaming may allow us to do something about the boredom we are feeling at the airport because of a delayed flight. And regarding the future, strolling through shops may trigger some ideas about a next trip to Sweden. Daydreaming can

thus be seen as participating to the elaboration of past, present, and future experiences.

Reframing Daydream and the Possible

A sociocultural psychological perspective on daydreaming enables us to integrate the propositions of psychoanalysis with Singer's constructive view. In effect, current cultural psychology has a processual and developmental approach to mind and considers the psyche and human experience as semiotically, culturally mediated. It sees mind as elaborating affective experience through signs, as well as being able to generate affective experience through signs; these results from our experience of interacting with other and the world they inhabit (Vygotsky 1975). Experiences can thus be apprehended in more or less concrete ways and more or less conscious ways (Salvatore and Zittoun 2011; Valsiner 2000, 2014, 2019).

For sociocultural psychology, human experience is future-oriented; through play, perspective taking, imagination, fabulation, and fiction, humans can relive their pasts, explore alternatives, and, especially, generate their future (Gillespie 2005, 2006; Stenner 2018; Vygotsky 1994). Daydreaming is thus understood as one variation of these semiotically mediated processes, building on past internalized experiences, now reconfigured in new ways, often through creative synthesis (Vygotsky 1971), and build new possibilities. From such perspective, daydreaming, like imagination, is not mere repetition of past traces; these processes rather participate to the expansion of experience (Pelaprat and Cole 2011; Zittoun 2019; Zittoun and Gillespie 2016). Both daydreaming and imagination demand that we decouple or disengage from the flow of common affairs, situated in the socially shared reality, to engage in what can be called distal experiences that escape the social and physical laws of that reality. Given its past theoretical anchorage, the notion of daydreaming emphasizes, more than that of imagination, the pervasive, background presence of the phenomena, as well as its roots or extensions in unconscious and affective activities, closer to dreams. However, many of the forms of daydreams documented by the literature, whether classical or more recent (Pereira and

Diriwächter 2008; Singer 1977), could be also considered as imagination.

In our proposition, daydreaming is seen as elaboration of experience and, more so, as a form of expansion of the possible. It can take the form of simply allowing us to leave the house to go to work or take the obvious form of coming up with a new idea or devising an unthought of solution. In any case, as a semiotic process part of the elaboration of experience, it can retrospectively participate in the sense-making of experience, to re-present experiences which have been so far not enough semiotically elaborated, presently mediate the relation to the real, or in a future-oriented manner, and pave the way to experiences to come. Daydreaming is thus part of creating the possible world in which we live.

Abstract

In this chapter, the way people consider possibilities in decision making are unpacked and explored. It begins by outlining the concept of rational choice – what a decision maker *ought* to choose. Specifically, it discusses how, for a

given decision, a rational choice can (or cannot) be determined. Whether people often make rational choices, and what can be done to shift people toward making rational choices more often. The chapter also portrays decision making in a human light: explaining how defining a rational choice and the decision process are constrained by human biology and behavior. The steps required to make a decision are delineated, and at each step, it is briefly discussed when and how people can diverge from what they *ought* to be doing or choosing. The chapter closes by discussing how people evaluate decisions after they have made them and the factors that affect the evaluation.

Keywords

Decision making · Rationality axioms · Bounded rationality · Heuristics and biases · Risk · Uncertainty

What Is Decision-Making?

The goal of this chapter is to introduce readers to the science of decision-making, with special focus on how possibilities are considered, compared and ultimately selected. It aims to highlight how for real life decisions an abundance of possibilities is dealt with by a decision-maker whose ability to process information is severely limited.

According to classical dictionaries, a decision is the act or a process of deciding, a determination arrived at after some consideration (Decision 2020) or a choice or judgment that one makes after a period of discussion or thought (Mayor 2011). The interdisciplinary science (Hardman 2009) that focuses on how decision-makers (people, organisms, machines) choose among possible options, based on their goals and beliefs (Hastie 2001) is Judgment and Decision Making, often shortened to JDM. The research of JDM can be broadly categorized into three separate streams. One is formal Normative Analysis that indicates how a decision *should* be made. For a given situation, this

analysis outputs what is termed the “rational” choice; the choice that a decision-maker who finds themselves in that situation *ought* to make. A second stream is Descriptive Analysis that shows how decisions are *actually made*. For a given situation, this analysis examines the choices people make and tries to explain the potential discrepancies between the choices made by individuals and the choice recommended by the Normative Analysis. A third stream of analysis focuses on Prescriptive Interventions to aid people to make better choices among possible solutions and improve their decision-making, also known as debiasing (Fischhoff 2012; Larrick 2004). Often, this stream of analysis tries to shift the responding of individuals (as indicated by the Descriptive Analysis) to better match the choice outputted by the Normative Analysis.

This chapter will explore the three streams of JDM research. It will examine across various situations how people should decide, how they tend to decide, and what can be done to resolve any discrepancies that may arise. In order to better understand decision-making, this chapter will begin by introducing the important concepts of rationality, cognitive limitations of the decision-maker, and cognitive miserliness.

Rationality, Cognitive Limitations and Cognitive Miserliness

Rationality

The core point of the Normative Analysis is to uncover which decision option a “rational” decision-maker should choose in a given scenario. Here, the notion of rationality refers to deciding in a way that is sanctioned by the axioms or rules proposed by normative theories.

Normative Analysis provides the framework for how decision-makers can make rational choices in accordance with a goal. Often, the proposed goal of the individual is to maximize their utility – the quantifiable benefit that results from actions (Begg et al. 2014). According to Normative Analysis then, a decision-maker

ought to always choose a possibility that will bring them the most benefit. In order to do this, an agent should follow rules that are structured in a way that, if violated, make such utility-maximizing choice-behavior nearly impossible in the long run. These rules are called axioms and four underlie standard utility theories: Completeness, Transitivity, Independence of Irrelevant Alternatives, and Continuity (Von Neumann and Morgenstern 1944). Axioms define relationships between preferences. For example, if at an ice cream store an individual chooses to purchase a scoop of strawberry instead of a scoop of vanilla, they are said to prefer strawberry over vanilla. Preferences are Complete when for any pair of alternatives, a decision-maker “knows what they want”. For instance, the individual knows whether they prefer strawberry to vanilla, or vanilla to strawberry, or if they are indifferent between them. Preferences are Transitive when the individual prefers strawberry to vanilla, and vanilla to chocolate, and because they prefer strawberry to vanilla to chocolate, they necessarily prefer strawberry to chocolate (i.e., if given the choice between strawberry or chocolate, that person would pick strawberry). Preferences are Independent when introducing an option like chocolate does not change preference between options strawberry and vanilla (i.e., the person will choose strawberry over vanilla with or without the third option of chocolate present). Finally, Continuity means that for any three alternatives with preferences as outlined above, there exists a unique probability p where a lottery with two outcomes: obtaining \$10 with probability p , or obtaining 0 with probability $1-p$, is equivalent to obtaining some amount of money for sure. This final axiom will receive more attention in subsequent sections.

Cognitive Limitations

If the goal of the decision-making process is to be normatively rational (i.e., to find the *best* solution), then even trivial decisions (i.e., “which flavor of ice cream should I order?”) can be a daunting task requiring an abundance of cognitive resources. Yet in practice, individuals handle the decision-making process with ease and most decisions are made quickly and with little effort. One

reason for this principle-practice discrepancy is the inherent limit to people’s processing capacity. Simply put, people cannot process an infinite amount of information, and therefore have to restrict the amount of information that is to be processed before making any sort of decision. Although across simple and well-defined situations people may indeed maximize their utility, they often deal with nebulous problems where maximizing utility is practically unachievable because of task complexity. In such cases people settle for satisfactory solutions (termed *bounded rationality*) by forgoing expending a large quantity of cognitive resources to obtain the highest possible utility for a choice that gamers a lot of utility for little cognitive cost. Naturally, determining exactly how much utility is “good enough” (and at what cost) leaves plenty of room for erroneous decision-making processes to enter.

The time and effort required to obtain and process information must affect how rationality is defined in realistic situations. As human beings are not hyper-powerful computers capable of processing infinite information, maximizing utility may be an unachievable goal. An offered replacement to the idea of maximizing utility is the level of aspiration: an ambition of the decision-maker to satisfy their goals in a sufficient way (Simon 1959). Simply put, one does not have to choose the ice cream flavor that will necessarily bring them the most utility, but merely a flavor that they will enjoy. Therefore, rationality can be defined at least in two ways. Indeed, another approach defines rationality as deciding in a way that is generally reliable and efficient for achieving one’s goals (Evans and Over 1996). The key message of this section is that human beings are necessarily imperfect, and as such, prescriptions of rationality that necessitate human perfection may not be appropriate (Todd and Gigerenzer 2012). In some conditions, the biased strategy is well-calibrated, and using normatively incorrect methods of deciding is practically equivalent to the use of normatively appropriate strategy (Domurat et al. 2015). In some other conditions, these “mental shortcuts” result in severe decision errors. In the next section, the limitations of human processing power are explored.

Cognitive Miserliness

For most decisions an individual will make during their lifetime, there exists a seemingly infinite number of possible alternatives from which they could choose. However, the human mind is not set up to exhaustively generate alternative choices. Rather, it is set up to make reasonably accurate decisions with as little effort as possible. One way this manifests is through the tendency to be a *cognitive miser*, that is to expend as few mental resources to complete a task as possible (Fiske and Taylor 1991). To illustrate, consider the following problem from Stanovich (2009):

Anne is looking at Brad, who is looking at Claire. Anne is married and Claire is not. Is a married person looking at an unmarried person?

A ubiquitous response to encountering this problem is that there is not enough information to solve the problem. This is because the marriage status of Brad remains unknown and a typical first glance would suggest that without this piece of information, the problem cannot be solved. This is how most people mentally represent the information in this problem:

Married → *Unknown* → Unmarried.

Importantly, this represents only the information provided directly in the problem. What is key is that more information can be inferred by simply testing the possible marital statuses of Brad. If it is assumed Brad is married the mental representation becomes:

Married → Married → Unmarried.

Here, the answer to the question (“*Is a married person looking at an unmarried person?*”) is YES. A married person (Brad) is looking at unmarried person (Claire). Now, consider a case in which Brad is unmarried. The mental representation becomes:

Married → Unmarried → Unmarried.

Once again, a married person (Anne) is looking at unmarried person (Brad). So, in all cases the answer is YES, a married person is looking at unmarried person. When explained, people are quick to realize the error of their thinking and wonder how they were unable to reach that conclusion in the first place. The problem is that people are cognitive misers – they tend to mentally represent only the information

that is stated directly and fail to fully flesh out the problem (Johnson-Laird 2012) or perform “cognitive decoupling” (Stanovich 2018). To decouple is to construct mental representations of possible alternative states and compare them to the presented problem – as was done in the above illustration. However, decoupling is difficult. It requires substantial cognitive resources and is antithetical to the tendency for humans to be cognitive misers (Stanovich 2020). Despite decoupling being necessary to the generation of possible alternatives, humans do not readily perform it and as a result often have very few alternatives to choose from.

Stages of Decision-Making

Due to the complex nature of decision-making, the processes involved in making a decision have been divided into the following sub-categories: defining a decision-maker; framing a decision problem and setting the goals; asserting the decision circumstances and hard or soft constraints; defining the set of criteria; gathering possible alternatives; judging the alternatives according to the criteria, and finally making a decision and evaluating it. The next sections of this chapter will explore each of these stages.

Defining a Decision-Maker

For every decision, the first question that must be asked and answered is, “who is making the decision?” Individuals, groups, and machines are all appropriate responses to such a question and the decision-making process diverges based on the answer. For the purposes of this chapter, the sole focus will be on the individual as the decision-maker. Readers interested in group or machine-based decision-making are encouraged to explore beyond this chapter (Kerr and Tindale 2004; Surowiecki 2004).

Setting Conditions and Framing a Problem

Next, a decision problem is somehow defined and described. When individuals are required to make a decision, they must outline the conditions under which they must make their decision.

Conditions

Decisions are made under one of three conditions: certainty, uncertainty, and risk (Luce and Raiffa 1957). These settings each uniquely impact how utility is calculated, rationality is defined, and what criteria require satisfying for the decisional problem to be solved.

A situation of certainty means that a decision-maker knows the outcomes that will result from a possible choice for sure. Imagine an individual who is considering one of four places to spend their next holiday (Table 1). If their preferences follow the rationality axioms, then it is possible to assign some values reflecting intensity of their satisfaction (*utility*) going to different locations and doing different things (Table 1, column “certainty”). Based on these utilities, the individual will be most satisfied if they head to the mountains and partake in hiking activities and least satisfied with staying home watching Netflix.

A more realistic approach to such a decision would be to consider the additional factors that may impact the utility of the possible choices. In this case, the expected weather of each location (see Table 1, column titled “uncertainty”) might modify the utility the individual expects to derive from each location. This creates a condition of uncertainty because the decision-maker cannot be sure of the utility that will be derived from each

destination, as it depends on external states of nature. While uncertainty adds complexity to the decision-making process, it does not necessarily make the expected utility calculation impossible.

An element of risk can be further considered, in which full information about chance is available. For instance, long-term weather forecasts can be examined in an attempt to predict the particular weather that will occur during the holiday (see Table 1, column “chances”). Finally, a decision-maker may experience ambiguity, a situation when there is incomplete knowledge of chance. Therefore, ambiguity lies somewhere between uncertainty (no information about chance) and risk (full information about chance). People largely prefer decisions under risk to decisions in ambiguity to decisions under uncertainty (Ellsberg 1961), as they prefer to have more information at hand, even if this information will not be used in praxis (Michailova et al. 2017).

Formulating the Decision Problem

Formulating a problem involves setting decision goals and identifying possible ways these goals could be achieved given the conditions surrounding the decision. Activating different goals can even affect an individual’s preferences. To illustrate the latter claim, in a landmark Tversky and Kahneman (1981) experiment, participants were

Decision-Making, Table 1 Three ways of framing a decision problem within three kinds of conditions (certainty, uncertainty, and risk) on the example of where to go on holidays

<i>Conditions:</i>	Certainty	Uncertainty				Risk			
		States of nature				States of nature			
		Rainy, cold, windy	Windy, cloudy, cool	Warm, no clouds	Very hot, dry, no wind	Rainy, cold, windy	Windy, cloudy, cool	Warm, no clouds	Very hot, dry, no wind
<i>Possibilities</i>	Utilities	Utilities				Chances			
Lakes, surfing	8	3	10	5	2	0.2	0.4	0.3	0.1
Mountains, hiking	9	3	7	9	6	0.2	0.4	0.2	0.2
Sea, beaching	6	1	2	7	9	0.1	0.1	0.5	0.3
Staying home, binge-watching	2	5	5	2	1	0.1	0.2	0.4	0.3

to choose between two ways of curing a new type of flu, threatening lives of numerous people. One vaccine was certain to save only some of the people, the other vaccine had a chance to save everyone and a chance to save no one. When the vaccine was said to *save* lives, people opted for the vaccine with certain outcomes; when the vaccine was said to *result in some deaths*, people opted for the risky vaccine. This reveals that it is possible to change decision-makers' risk preferences through highlighting different goals merely by slight changes to the wording of a problem: people prefer receiving certain gains (i.e., lives saved), but are risk-seeking when it comes to avoiding losses (i.e., deaths).

Decision Space of Alternatives

The collection of possible solutions one generates when considering how to achieve a goal is called decision space, and such possibilities are called alternatives. The human mind has evolved to reduce the decision space to a manageable size, for example, by removing some alternatives even prior to their consideration. While this improves the ability to make the plethora of decisions humans are required to make in their daily lives it necessitates giving up the possibility of having complete information for nearly every choice.

Although there are often many ways that an individual could go about achieving a goal, there are usually hard and soft constraints that move some alternatives out of consideration. Hard constraints are settings that impact a decision but are independent of the decision-maker. Soft constraints are settings that arise internally from the decision-maker. Some examples of hard constraints are: when purchasing ice cream one can only choose from the available options; when buying furniture, one must keep in mind the dimensions of the room they intend to furnish. Regarding soft constraints, some investors refuse to purchase stock in so-called sin companies (i.e., in firearm manufacturers or tobacco companies), objecting on the grounds of their morality (Niszczota and Białek 2020). Additionally, soft constraints can be the result of the limited processing capacity (i.e., not being able to remember

every available alternative) or from processes meant to simplify the decision process to prevent having to expend much cognitive effort.

In reading this chapter, one is necessarily declining to engage in a large range of other alternatives, such as watching a movie or working out. It is unlikely that one values learning the content of this chapter over any other possible thing one could be doing instead. Rather, reading this chapter may have been the best alternative compared to just a few other alternatives that may have come to one's mind (e.g., working out). This information is shared to help illustrate the phenomenon of opportunity cost neglect (Alchian 1968). That is, the cost of reading this chapter is not only the time invested, but also the forgone benefits of alternative activities. Often, when choice alternatives that were not evaluated are presented to an individual, they can be given undue weight in the decision process. As painful as this realization may be, neglecting these opportunity costs does not necessarily mean a bad decision was made. Generating and considering possible alternatives to a course of action can be cognitively taxing, requiring a large amount of time and resources to be expended. And it is an action itself, so if one decided to optimally select what to do, one would in fact be thinking instead of doing the thing one wanted to do. By neglecting most and considering only a short list (or no list at all) of alternatives, a choice can be made quickly and efficiently.

Another phenomenon related to navigating the decision space is the omission bias, a preference for options that do not require action (Spranca et al. 1991). People display omission bias because they are far more sensitive to direct outcomes of their actions compared to consequences of omissions (Royzman and Baron 2002). One of the reasons for it is that the causal link in the direct outcome is far more obvious (Waldmann et al. 2017). For example, people see a direct link between vaccination and its possible negative side effects, but not between no vaccination and the possibility of falling prey to the preventable disease. This direct link leads some to refuse to vaccinate even if its side-effects are far less severe

than the disease (Ritov and Baron 1990). So, our mind architecture makes us select an inferior choice option because of how the choice problem is formulated.

Decision Analysis: Making a Decision and Evaluation

Once some number of alternatives have been generated, the next step of the decision-making process is to determine the alternatives that pass specific criteria or meet the goals of the decision-maker. This is a complex process, and several normative models have been developed to say which strategy ought to yield the best results in satisfying one’s goals. There are several strategies, because they are aimed to satisfy preferences which can vary across individuals. For instance, one person might strive to achieve the greatest amount of utility possible regardless of the risk involved. Another person may prefer to play it safe and minimize the possibility to experience loss or regret. So, normative strategies are dependent on preferences.

Certainty

When the utilities for each available option are known to the decision-maker, the act of choosing is seemingly easy – it is possible to select the alternative with the highest assigned utility. However, even in cases where certainty is present, decision-making is rarely simple. One consideration to keep in mind is the advanced calculation that may be required, or where it is impossible to find a solution in a reasonable timeframe. Consider a superficially simple problem: the traveling salesman problem. In it, the goal is to find the shortest route for the salesman to travel that starts from and ends at their home and requires them to

pass through N cities. Importantly, the exact distance between each city is known (Lenstra and Kan 1975). When the number of cities (N) is a low number, such as 3, then only 6 possible routes exist – finding the shortest route is straightforward. Yet, when N reaches a slightly higher number, such as 10, the number of possible routes is more than 180,000 – finding the shortest route here becomes a much more daunting task despite being in a condition of certainty. For the best route between 20 cities, the task becomes so complex that an advanced computer would require about two years to find it. In cases like these, shortcuts and decision strategies aid individuals in finding a solution.

The traveling salesman problem had only one criteria of evaluation: the shortest path is the best. However, when deciding, an individual may want to consider multiple criteria. For example, when purchasing a house, its price, space, condition, location, and distance from work are all important factors. They seem difficult to combine, as they are different qualities/measures, and even worse, sometimes contradictory (e.g., one would probably want the lowest price and the greatest living space). This often further complicates the decision-making process. How might someone go about finding the optimal solution in such instances? Consider the holiday example below in Table 2. When analyzing possible destinations for a holiday, joy, achievements, and sociability are criteria that might be considered. Here, the numbers represent an individual’s subjective judgment of how a given destination satisfies the criteria. Assigned are also weights which express differentiated importance of the criteria.

First, notice that some possibilities are dominated by others. That is, under each criterion,

Decision-Making, Table 2 Multi-attribute decision problem

	Criteria (attributes)			
	Joy	Achievement	Sociability	
Possibilities	0.50	0.15	0.35	MAU
Lakes, surfing	6	10	10	8
Mountains, hiking	10	8	8	9
Sea, beaching	4	3	10	6
Staying home, binge-watching	1	1	4	2

staying home is worse than going to the beach. So, the choice alternative of staying home can and should be immediately discarded and should not receive further consideration. With the three alternatives remaining, various time consuming and effort requiring methods to utilize more information can be employed. One such method is multi-attribute utility analysis (MAU; Keeney and Raiffa 1993). MAU uses all the information available, and allows the decision-maker to compensate low scores on some criteria with higher scores on other criteria. For example, relatively low joy in surfing is compensated by high achievement and sociability scores. To estimate the MAU, one needs to evaluate all alternatives on all criteria, and weight the importance of each criterion (as already done in Table 2). Next, one needs to multiply weights and values for every alternative, and select the alternative which has the greatest sum of all these products. For mountains, the MAU calculation is $(0.5 \cdot 10) + (0.15 \cdot 8) + (0.35 \cdot 8) = 9$, and it is the highest value among all alternatives.

Although this weighed additive strategy uses all the information, it is effortful, and in practice, people tend to act as cognitive misers and simplify decisions rather than expend great effort to resolve them (Payne et al. 1993). For instance, one could employ a Lexicographic Strategy instead. Here, one compares the alternatives on the attribute deemed most important to them and ties are resolved by evaluating the tied alternatives on the next most important attribute. If joy is the most important criterion, one should go hiking, as it promises the greatest joy compared to other locations. One can decide even quicker using a Satisfaction Strategy (Simon 1959): set minimum requirements and then choose the first possibility that meets them. Let it be 5 for joy and 9 for other criteria. In our example, surfing on lakes would be chosen. There is also a possibility to combine these strategies and eliminate alternatives which do not meet the minimal requirements on criteria considered according to their importance (Tversky 1972). We would, considering joy, discard staying home and beaching in the first step. In the second step, we would consider sociability, discarding hiking, and finally choose surfing.

Uncertainty

Things get more complicated under uncertainty, as external states of the world influence the utility one can derive from a given option. Now, an individual should incorporate the natural uncertainty of the world into their decision-making process. Of course, normative approaches have provided methodology to do this as well. For example, one method allows the individual to take into account uncertain conditions and their attitude toward experiencing good and bad things (Luce and Raiffa 1957). To better understand these strategies, Table 3 is a modified version of Table 1.

If a person is good at dealing with negative outcomes, then they can apply an optimistic rule of “maximax” – choose the alternative that contains the greatest potential utility to be gained regardless of the other possibility utilities it could provide. In the holiday example, going to lakes allows the person to experience the greatest amount of utility – 10.

If the decision-maker wants to protect themselves from the worst experience, they can use the “maximin” rule – choose the alternative with the highest utility among the lowest-utility possibility for each alternative. In the holiday example, the worst outcomes for each destination are compared (2 for Lakes, 3 for Mountains, 1 for Sea and Home). So applying the maximin rule will lead the individual to choosing the mountains as its worst outcome is superior to the rest.

Alternatively, an individual looking to minimize the potential for regret can follow an opportunistic “minimax” rule. In plain words, regret is the difference between the experienced utility of what one selected and the highest possible utility one could have experienced had they selected the best available alternative for a given state (columns “regret”). In our holiday example, consider the bad weather. Here, the best possible outcome is staying home, and all other choices result in a regret equal to how much worse their utility is. For every alternative, the greatest regret is identified (7 for Lakes, 3 for Mountains, 8 for Sea and Home), and the alternative that has the smallest value of the maximal regret (i.e., Mountains) is selected. Alternatively, one can apply the

Laplace Principle of Insufficient Reason and, not knowing chances, assume all the weather states are equally probable which is equivalent to averaging outcomes for a given alternative. Here, the most attractive location would again be the mountains with an average utility score of $(3 + 7 + 10 + 6)/4 = 6.5$.

As stated above, selection of the strategy depends on preferences. In this instance, the preferences are one's attitudes toward positive and negative outcomes.

Risk

To be rational, a decision-maker should consistently apply a decision criterion to each possible choice option. However, people often use different criteria to evaluate different options. For instance, when people were proposed to take part in one of two lotteries: L1: 25% chance of winning \$30, and L2: 20% chance of winning \$45, a majority (58%) chose the second option. However, most people (74%) chose to receive \$30 for sure instead of playing a lottery with 80% chance to earn \$45 and 20% chance of winning nothing (Tversky and Kahneman 1981). When deciding between two gambles, people select the one with highest expected utility. When a lottery is substituted with certainty, people tend to prefer guaranteed gain over a non-guaranteed option that is expected to provide the greatest utility.

There are methods combining probabilities of particular payoffs with their utilities. We can simply multiply the probability of a payoff by its utility, returning four such products for each holiday destination (i.e., for rainy, windy, cold and very hot weather). According to subjective expected utility theory (Savage 1954; Von Neumann and Morgenstern 1944), a decision-maker should choose the alternative with the highest expected utility, that is, the greatest sum of these four products (column "SEU"). Having computed that for all the four alternatives, we should decide on hiking in mountains, because it has the highest subjective expected utility of 6.4.

Fallacious Criteria of Making Decisions

To save some effort in managing the decision space (abundance of choice alternatives) people defer to various strategies. Next some of the

fallacious strategies employed will be reviewed. By fallacious it is meant that the strategy often leads to suboptimal choice at the benefit of saving time and effort usually required to apply a more logical decision strategy.

Imagine a person visiting a website that asks them to accept the site's cookies policy and allow it to make use of the person's private information. This person can opt out, but this requires to dive into advanced settings and requires several steps. Now, consider another website that asks this person whether they allow the website to use the information or not. Are they equally likely to provide access to their data? Experimental evidence suggests people are far more likely to allow it in the first case (Samuelson & Zeckhauser, 1988).

To understand why this happens, one needs to refer to a concept of defaults, a course of action that will happen unless actively changed. People largely accept the default option unless prompted to consider the other possibilities. This rely-on-the-default strategy allows one to save effort, which would be otherwise required to decide between two equally attractive outcomes. But this strategy also makes people often select the inferior option simply because the inferior option happens to be the default. In politics, it displays as so-called system justification, an assumption the world should uphold the status quo, simply because it was designed this way in the past (Jost et al. 2004). A Nobel Prize was awarded to Richard Thaler for his work on defaults and its use to facilitate desired decision-making, so-called *nudge* (Thaler and Sunstein 2008).

Another error in reasoning is using the criterion of sunk cost, when one decides to continue with one course of action only because of the resources previously invested in it (Arkes and Blumer 1985). The sunk cost bias occurs when an individual continues with an endeavor that they would have otherwise stopped had they not already invested some resources. As resources expended in the past cannot be recovered, they should not affect present decisions. However, they often do. For example, consider patients A and B. Each patient is presenting with the same symptoms of the same disease and each require the same treatment. In fact, the only difference between patients

A and B is that patient A has been receiving treatment for the past several months. Often medical professionals will continue the treatment of patient A that they would not otherwise administer to the identical patient B simply because they have already invested resources into treating patient A (Turpin et al. 2019; Wilkinson et al. 2019). The allure of honoring sunk costs may be even stronger in moral domains such as animal testing, as people are willing to continue sacrificing laboratory monkeys to develop medical cures even after learning that further development of the cure will bring no actual benefit (Meyers et al. 2019).

Evaluation of a Decision: A Hindsight Bias and Hedonic Adaptation

How one evaluates the quality of a decision is of high importance. Often, people evaluate decisions based on their outcomes, largely ignoring the process that led them to choose a specific option. They often do this by inspecting the outcome, which counterintuitively, is not a good strategy. A reality of the decision-making process is that “right” decisions will not always lead to good or wanted results. Similarly, it is possible that “wrong” decisions produce good or wanted results. For example, one can profitably invest in a project that has only a 10% chance of providing a return, and another person can lose their investment in a project that has a 90% chance of a return of the same value. Yet, despite the positive outcome, the first decision-maker was simply luckier than the second one; a decision to invest in the 10%-chance project would result in much worse outcomes in the long run.

Having to experience the outcomes, people usually tend to evaluate decisions as more or less good. Normatively, the decisions are made right when they are in accordance with a decision-maker’s preferences and consequently follow assumed methods, algorithms, and heuristics, according to the knowledge at the time of the decision. Two dangers that await a decision-maker who has made a decision and experiences its consequences are: hindsight bias and hedonic adaptation.

Hindsight bias relates to judging past events as more predictable than they actually were (Fischhoff 1975). Participants read an account of historical events with one of several outcomes and estimated the probability of possible endings. Across experiments, participants consistently viewed the outcome they had received as having been more likely than did those who had not been informed of an outcome (Klein et al. 2017). This effect stems from a confusion between one’s current knowledge and memories of the knowledge one possessed when deciding. Nowadays, people might live in impression that the COVID-19 pandemic was easy to predict and it was obvious what interventions and on what scale should be implemented (Redelmeier and Shafir 2020).

When deciding, an individual can project how their life will change if they achieve a goal. Individuals also tend to overestimate the intensity and duration of their emotional reactions to the goal’s outcomes (affective forecasting error, Wilson and Gilbert 2005). However, when people experience the consequences of a decision, the affective intensity of favorable and unfavorable experiences is reduced and people adapt to them (hedonic adaptation, Frederick and Loewenstein 1999). Yet, people adapt to positive outcomes faster than to negative outcomes (hedonic asymmetry, Frijda 2007). Hence, once the outcomes are known, the evaluation of the decision process can be distorted, making it subjectively less bad.

Summary

Deciding requires coming up with possibilities and comparing them. In real life, in contrast with artificial experimental tasks, people are able to generate almost unlimited number of possible solutions to a given problem. This makes decision-making taxing and necessitates that people adopt strategies to limit the number of possibilities they consider. Therefore, a reduction of possible choice alternatives, even if it is completed unreflectively, is often beneficial to the decision-making process because it reduces a complex decision to a manageable decision.

This simplification of a problem is not necessarily a bad thing, as the optimal decision does not require every possible solution to be known. Nor, as has been covered, does knowing all the possibilities even guarantee that one will make the best decision. Generating and considering each possible alternative is often taxing beyond one's limited cognitive capacities. Further, even having the mental resources available people tend to be cognitive misers, they often will not want to perform the necessary decoupling. With the choices available to them, Normative Analysis can be used by making an expected utility calculation, keeping in mind conditions of certainty, uncertainty, and risk. More often, people defer to strategies meant to conserve cognitive resources at the cost of picking a satisfactory, though perhaps not optimal, solution. What is critical is that normatively incorrect solutions can be at times most beneficial, yet they will be inferior to normatively correct solutions in the long run.

As time progresses, so too will the three streams of research in Judgment and Decision Making. The scientific canon will continue to grow as further exploration takes place into prescriptive models of decision-making, descriptive models of decision-making, and ways to merge the gap between the prescriptive and descriptive. An interested reader is encouraged to dive into any of the referenced publications to learn more about possibilities in decision-making.

Deliberation

Leandro De Brasi

Universidad de La Frontera, Temuco, Chile

Abstract

Deliberation involves the interpersonal exchange and evaluation of reasons and counter-reasons, in which each party attempts to rationally persuade the others, rather than

manipulating or bargaining with them. This group deliberation is crucial for the generation of epistemic goods, such as knowledge and reasonable beliefs, given that it helps us eradicate possible errors. But it is a familiar fact that groups often perform suboptimally and indeed only under particular conditions deliberative groups can tap this epistemic potential and in turn avoid deliberative distortions, such as polarization and domination. This entry then focuses on certain positive epistemic possibilities that group deliberation can foster and on certain structural and personal conditions that enable such potential. Regarding the structural conditions, the deliberative group needs to instantiate some cognitive diversity concerning opinions, knowledge, and skills. Regarding the personal conditions, the individual deliberators need to possess an intellectually humble and autonomous character.

Keywords

Deliberation · Cognitive bias · Prejudice · Epistemic potential · Cognitive diversity · Intellectual character · Epistemic injustice

Deliberation is the process by which individuals weight the merits of competing reasons in discussion together. In particular, the individuals, conversing together, jointly explore the plausibility of some claim, each bringing a slightly different perspective to bear. The individuals are meant to defend those perspectives, which are challenged by their interlocutors. These challenges cannot be ignored and reasons (some of which are tailored to specific objections raised) are evaluated in this exchange. For example, one party may advance a reason in favor of some claim and another one may respond by introducing a counter-reason or defeater that speaks against the claim; then the first party may introduce a defeater of the defeater or concede the original reason offered has been defeated – or weakened to certain extent – and perhaps introduce some new reason, and so on. Eventually they weight the reasons for and against to see how strong the case for the claim is. In this sort of deliberation, each party attempts

to rationally persuade the other parties by them appreciating the quality of the reasons (not by, say, manipulating or bargaining with them). So deliberation is the interpersonal practice that involves the production and evaluation of epistemic reasons for and against some claim and its consequent possible revision (De Brasi 2020a).

This interpersonal exchange and evaluation of reasons and counter-reasons can be crucial for the generation of epistemic goods, such as knowledge and reasonable beliefs, given that it helps us eradicate possible errors. So, in this sense, this sort of group deliberation can foster epistemically better formation and updating of beliefs as well as more effective decision-making (given its dependence on the epistemic quality of the beliefs in which it rests).

One obvious way in which interpersonal deliberation can help eradicate possible errors has to do with the dispersal of knowledge. Different people often bring to the discussion different knowledge. This additional flow of information can bring to the discussion new reasons and defeaters and so increase the chance that erroneous views be corrected (Fearon 1998). But people can be diverse in other ways too. For example, people can also vary with respect to the cognitive skills they exploit to target some issue (or how they use them). And this too can serve the aim of correcting errors. For example, by pooling the limited and fallible cognitive abilities of two deliberators, they can increase the chance to pick out errors either because one thinks (on her own, given her abilities), say, some possibility that the other would not have thought (and vice versa) or because some possibility is put forward that is the brainchild of their abilities and interaction (and neither of them could have thought of it on their own).

Another, less obvious, reason has to do with neutralizing certain cognitive shortcomings. To appreciate this, consider two pervasive forms of faulty thinking. The confirmation bias is the natural and pervasive tendency to find reasons for one's beliefs and against beliefs one opposes, which does not apply to the evaluation of reasons (Mercier 2017). However, deliberation also involves evaluating reasons and when it comes to evaluating reasons that one opposes, we

scrutinize them for longer and subject them to much more extensive refutational analysis than those that agree with our prior beliefs (Edwards and Smith 1996). Given this disconfirmation bias, we are more inclined to detect errors in reasoning for a conclusion with which, to begin with, we disagree. Relatedly, research on the bias blind spot shows that one is better at detecting cognitive biases in others than in oneself (Pronin et al. 2004). This means that one is naturally a more rigorous evaluator of opposing views.

Moreover, one can recognize and concede to a good reason against one's view. In fact, even when people are confident about some view, they can change it if the reasons suggest it (Chan et al. 2017). But, of course, these biases suggest that probably one cannot alone come up with some such reasons against one's view and so deliberation can again prove itself epistemically useful given that it allows for the interaction of individuals with disagreeing views. Given this interaction, both the confirmation and disconfirmation biases become part of an elegant and useful way of dividing cognitive labor (Mercier and Sperber 2017). On the one hand, the confirmation bias makes each individual come up with a (relevantly strong) case in favor of their own views. And although one does not search for reasons against one's view, the other, who disagrees with one, does. So each presents the best case for and against some view. On the other hand, the disconfirmation bias makes each individual a rigorous judge of the other's reasons. Although one does not scrutinize one's reasons assiduously, the other, who disagrees with one, does: each one controls the quality of the reasons provided by the other. So, given that we can recognize and concede to a better reason, the less error-prone case – given the available evidence – is likely to prevail. In particular, these individual cognitive biases can be neutralized by thinking together in a critically engaged manner and so, in so far as deliberation is pursued cooperatively, increase the epistemic performance of the group.

As just seen, group deliberation has the potential to correct possible errors due to the pooling of knowledge and skills and the neutralization of cognitive shortcomings, and so we have

collectively better chances to acquire epistemic goods. However, these positive epistemic possibilities of group deliberation are not simply realized by merely assembling individuals into a group. In other words, these are conditional possibilities that would, if realized, promote epistemic goods (and, minimally, remove false beliefs). But they are not easily realized. As much research focusing on the negative aspects of group dynamics has shown, groups are notoriously fallible and often perform suboptimally, making poor decisions and some even resulting in fiascos (e.g., Janis 1982). The phrase “a camel is a horse designed by a committee,” allegedly remarked by Sir Alec Issigonis, captures the familiar fact that sometimes groups end up performing worse than their average median member. There is much ineffective group collaboration and researchers have tried to understand the inhibitors and facilitators of adequate group performance (e.g., Sunstein and Hastie 2015). This entry considers certain structural and personal conditions that enable the above epistemic potential of group deliberation, hence focusing primarily on the facilitators of adequate group performance. In particular, in order for this epistemic potential to be tapped, the deliberative group needs to instantiate a certain cognitive diversity and the individual deliberators need to possess a certain intellectual character. Having said that, next, a couple of common deliberative distortions that are the result of certain inhibitors, such as cognitive homogeneity and prejudicial stereotypes, are presented in order to introduce these structural and personal conditions, although more emphasis will be made on the latter ones.

Polarization and Cognitive Diversity

Deliberation can lead to epistemically good outcomes but whether it does so depends partly on certain structural conditions holding. It has already been noticed the role that diversity of knowledge and cognitive skills play in promoting these benefits. But diversity of opinion is also required within the group if members are to search for different reasons and to assiduously evaluate

opposing views (and so, as one would expect and as research has shown (Nemeth et al. 2001), techniques such as devil's advocate are not effective given that the voicing of authentic positions is required). Indeed, deliberation seems to be epistemically harmful in the absence of this diversity. After all, homogeneous groups may fail to produce reasons against their shared beliefs and members may provide each other with additional reasons supporting them. This homogeneity can promote group polarization: that is, the members of the group end up with more extreme beliefs than they had prior to deliberation (Isenberg 1986).

This polarization can result, as just seen, from the sharing of confirmatory information. Another process that can bring about group polarization is social comparison: in this case, the polarization results from in-group comparisons. Even if the group does not share information, its members attempt to maintain their reputation and self-conception by emphasizing the attitudes they perceive to be normative within the group (Sunstein and Hastie 2015). But this again is likely to happen only in a group of likeminded people, so the above group heterogeneity can also remedy group polarization due to social comparison. In any case, the evidence in favor of consistent and significant group polarization in deliberation is found only in homogeneous groups (e.g., Levendusky et al. 2016). So a purely structural condition concerning the composition of the group, which successfully promotes the relevant cognitive diversity, can help suppress this deliberative distortion.

Domination and Reciprocity

Other distortions, such as domination (Sanders 1997), can occur in cognitive heterogeneous groups and so the above structural specifications cannot be sufficient to counteract them. Domination concerns the move of the overall group opinion toward the views of the socially privileged members. To appreciate how domination can occur in a cognitively heterogeneous group, consider that minorities within such a group might self-silence themselves (say, for fear to be

ridiculed, stigmatized, or some other social punishment). Of course, a group norm that welcomes dissent can nudge the minority to speak up (Paluck and Green 2009), but whether someone is then listened to when speaking is another issue. In fact, people might not listen to others because of differences in social identity. Take, for example, the case of gender. Many cultures, to a bigger or lesser extent, have led to a gender gap in terms of self-confidence: particularly, women experience a deficit, relative to men, in expectations about competence (Beyer and Bowden 1997; Karakowsky et al. 2004). These expectations of course affect whether men ignore or listen (more or less) to what women say, so women's ideas often have less impact or are blatantly suppressed in mixed-gender groups. Moreover, the systematic occurrence of such interactions can affect the confidence of women.

These competency-expectations are often the result of implicit prejudicial stereotypes (Brownstein and Saul 2016). Of course, people frequently employ identity-based stereotypes and they are not always at fault in doing so (indeed, such employment of stereotypes is a useful heuristic as long as they embody true generalizations and, in fact, we must employ them in order to engage in effective real-time interaction with people). But prejudicial stereotypes are false stereotypes: they wrongly connect a given social identity with some particular quality. So, given that these prejudices can affect the attention someone is paid in a deliberative interaction and damage someone's confidence on her ability to argue, they can contribute to the domination of one subgroup over another one (i.e., moving the overall opinion of the group towards the opinion of the dominant subgroup).

In fact, for the above positive epistemic possibilities to realize, a certain reciprocity needs to be instantiated. In particular, for the deliberation to involve a back-and-forth of reasons that can allow the better (less error-prone) reasons to prevail, it requires to be an interactional, two-way communicative exchange. Importantly, this process of giving and taking reasons includes responding to the reasons others have for their views and against one's. In this sense, deliberation is a reciprocal

process, where reasons are not only introduced by the different parties but also responded to. For this to be the case, it is not only important to give voice to the different viewpoints but also to listen to them. It is clear then that if there is to be a to-and-fro of reasons, interlocutors need to listen to each other (of course there are other forms of communicative receptivity aside from this aural one, but for simplicity sake here the focus is on listening).

Importantly, this listening needs to be equally attentive to all parties: in other words, the taking in of others' reasons should not be restricted to some of the reasons voiced in the deliberation. So proper deliberation requires attentive silence in order for one to listen to others, not merely remaining silent so to respect their right to express their views. Moreover, it is not enough simply to attentively listen to the others' reasons (let alone hear them, like one hears a noise). One is also to carefully listen to the others' reasons if one is to respond appropriately to them. One is to make the effort to adequately grasp the other's position (i.e., to understand the other's reasons) and for that careful, effortful listening is required. So, if deliberation is to be a dialogue in which we really address each other's reasons, as opposed to a series of rather disjointed monologues, deliberators need not only listen widely to all deliberators' reasons but also listen carefully to understand their reasons correctly and be able to respond appropriately (cf. Brownell 2016; Paulus et al. 2019).

Certainly, prejudices can more or less affect, as mentioned before, this listening. For example, we normally consider the trustworthiness of the sources before considering the reasons offered by them (Han et al. 2009; Hovland et al. 1953). In these assessments, prejudices can, and normally do, interfere (Perloff 2017). Stereotypes related to social identities concerning gender, race, sexual orientation, and religion, to mention some, can make people not to listen to someone. In other words, prejudices can interfere with listening widely. Moreover, in cases where the interlocutor is not completely discredited, prejudices can interfere with listening carefully, given that the (unfairly) lower credibility attributed to the

interlocutor can render it pragmatically irrational to spend the cognitive resources to make the effort to be as charitable as possible about the viewpoint offered and hence to promote proper understanding.

These are cases of epistemic injustice, where less credibility than deserved is attributed to someone's informative and argumentative assertions due to a negative identity prejudice attaching to them (Pohlhaus 2017). In these cases, an undeserved systematic harm is done to the person. More precisely, if we distinguish, following Miranda Fricker (2007), between primary and secondary aspects of the harm, the primary harm to individuals is in their capacity as epistemic agents and it is a species of insult or disrespect. The secondary harms seem to be varied. For one thing, and as seen above, experiencing constant credibility deficits can damage the epistemic confidence of the individual. For another, and importantly for present purposes, when identity prejudices cause reduced credibility judgments, reasons can fail to have the rational force that they ought and so they can affect the epistemic performance of the deliberative group. In short, the epistemic force of the reasons does not determine the deliberative outcome, which detracts us from the aspiration to be guided by the better reasons. So domination, and in particular those cases involving epistemic injustices, is likely to require, unlike polarization, changes in the psychological make-up of individuals if it is to be counteracted. Put differently, to reap deliberation's epistemic benefits, it is likely, at least partly, to require certain personal conditions and not only structural ones.

Intellectual Character

Cognitive diversity regarding opinion, knowledge, and skill within the deliberative group is necessary but not sufficient to realize its epistemic potential. To counteract domination and in turn promote the required deliberative reciprocity, the deliberators need to possess a certain intellectual character. For example, this reciprocity requires a certain degree of intellectual humility. This is so if

intellectual humility is understood as the cognitive habit that foils both intellectual arrogance and deprecation: neither does the intellectually humble person overestimate her knowledge and other epistemic goods as well as epistemic capacities nor does she underestimate them (De Brasi 2020b). Particularly, intellectual humility reduces intellectual arrogance (without underappreciation of one's beliefs and capacities) by promoting a doubting attitude owing to the recognition of our fallibility (due to, say, biases and prejudices) and our limitation (due to, say, our finite cognitive power and time). This dimension of humility makes clear how it can render one open to engage in interpersonal deliberation. Moreover, intellectual humility also involves a disposition to change and make up one's mind even due to others' opinions. After all, it seems that if the above recognition does not impact on one's opinions, then it is difficult to think of it as such. This dimension of humility makes clear how it can help one actually depend epistemically on others in certain circumstances. So intellectual humility can be understood as some sort of confidence management of one's beliefs and epistemic capacities (cf. Kidd 2016). It is clear the potential that humility *qua* confidence-management has to help us counteract domination, including those cases which are due to epistemic injustices, since it helps us to fairly appreciate the contributions of interlocutors. Indeed, such well-calibrated humility helps us to listen widely and carefully to and engage with them.

Moreover, to realize deliberation's epistemic potential not only is the individual required to be intellectually humble but also intellectually autonomous. This is so if intellectual autonomy is understood as the cognitive habit that reduces sheer epistemic dependence on others by promoting a willingness and ability to think critically for oneself in judging views, without capitulating to hyper-individualism (De Brasi 2020b). In other words, one has the dispositions and attitudes to self-govern intellectually, which include, among other things, seeking reasons, demanding reasons, and assessing for oneself reasons and sources of them. So, given that, as seen, each party controls the quality of the reasons provided by the

opposing party and tailors their reasons to the objections raised in epistemically beneficial deliberation, these dispositions and attitudes to critically assess also play a central role in fostering deliberation's epistemic potential. So both humility and autonomy are required of deliberators if they are to take advantage of such potential.

Further, intellectual autonomy is not in tension with intellectual humility. Intellectual autonomy is not a matter of sheer epistemic independence (Fricker 2006) and so being intellectually humble, which entails openness to epistemic dependence, is not incompatible with being intellectually autonomous. Indeed, intellectual autonomy involves some sort of dependence management. But one should not rely on others blindly, and intellectual autonomy, *qua* dependence-management, requires that one be able to discriminate between the epistemically good and bad reasons that others offer us. So not only is intellectual autonomy not in tension with intellectual humility (the former involves the management of our epistemic dependence and the latter the management of our epistemic confidence so to be open to such epistemic dependence), but it also helps us foster the required reciprocity by critically responding to the other's reasons.

Conclusion

It is hard to collaborate successfully, as much research on group dynamics shows. Deliberating with others can anyway increase our epistemic performance by eradicating possible errors in our belief system and so in our decision-making. But only under certain conditions groups can tap this epistemic potential. After introducing the possible epistemic gains to be had by group deliberation (namely, the correction of errors due to the pooling of knowledge and skills and the neutralization of cognitive shortcomings, and so the promotion of epistemic goods, such as knowledge and reasonable beliefs), this entry considered certain structural and personal conditions that promote such deliberative potential. In particular, on the structural side, it was seen that a certain group composition, which instantiates diversity of

opinion, of knowledge and of skill, is required. On the personal side, it was seen rather more extensively that, to reap the epistemic benefits, the individual deliberators seem to need to instantiate a certain intellectual character; more specifically, to be intellectually humble and autonomous. The above should not suggest that the personal has a certain kind of primacy over the structural and both character and structure are important ingredients to realize the epistemic potential of group deliberation.

Moreover, given that deliberation can have a crucial role in our everyday individual and social lives in order to better conduct them epistemically, one would expect that learning to adequately engage in it would be a priority of the educational system. In fact, if this system aims to enable personal flourishing, to form competent democratic citizens or merely to provide people with the cognitive capabilities to be able to acquire epistemic goods for themselves and with others (De Brasi 2020a), there is a good case for the educational commitment to help develop intellectually humble and autonomous character in people. If this is so, a structural, educational modification for the development of this intellectual character might be required in order to further enable the epistemic potential of deliberative groups.

Design Thinking

Samira Bourgeois-Bougrine
Université de Paris, Paris, France

Abstract

Design thinking (DT) is a human-centered approach to innovation that implies empathy as an innovation mindset to understand the latent needs of users observed in real settings. Those observations generate insights, which are translated into innovative products through iterations with quick-and-dirty prototypes in order to collect feedback from the field and users. Despite its growing popularity, several scholars have highlighted the lack of academic rigor in DT and have reported several limits such as its inability to support radical innovation. This entry will describe the process, challenges, and limitations in DT, as well as ways to open up the field of the possible in DT.

Keywords

Innovation · Design thinking · Human-centered Design · Needs · Empathy · Users

Introduction

Design thinking (DT) is a human-centered approach to innovation that draws from the designer's toolkit to integrate the needs of people, the possibilities of technology, and the requirements for business success (Brown 2009). DT emphasizes empathy as a state of mind to

innovate, focused first on understanding the latent needs of people through observation in real contexts. Indeed, DT starts by exploring the needs, dreams, desires and behaviors of the people that will be affected by the imagined solutions (e.g., products, services, environments, organizations). The guidelines for DT were made popular by the design and innovation company IDEO as well as Stanford University. Managers and practitioners in engineering design are increasingly integrating design thinking to stimulate innovation and DT as part of the curricula in many renowned management and engineering schools (Bourgeois-Bougrine et al. 2018).

Despite the growing popularity of DT, it should be mentioned that this is not a new process, “it is a new name for an old method” (Iskander 2018, p.2). Iskander (2018) considers that DT is poorly defined, based more on anecdotes than data, and is little more than basic common sense. Recent analysis of the uses of DT in industry (Carlgren et al. 2016, p.354) showed that “despite education and training in DT, interviewees described how many employees found it difficult to apply it in their own contexts after training.” The present entry will describe the DT process and address its limitations and possible ways to enhance its process.

The Design Thinking Process

DT emphasizes empathy as a state of mind to innovate, which begins with understanding the latent intellectual, physical, and emotional needs of people. It includes a set of tools to help designers move through five iterative steps: empathize, define, ideate, prototype, and test. These stages are the core components of the “three spaces of innovation” (Brown, Katz 2011, in Bourgeois-Bougrine et al. 2018): inspiration (e.g., the problem or opportunity that motivates the search for solutions; empathy-definition), ideation (e.g., the process of generating, developing, and testing ideas), and implementation (e.g., the path that leads from the project room to the market; prototype-test). These steps involve the art of thinking through drawing (visual thinking),

ethnographic research and other sources of inspiration (science fiction, biomimicry, cultural and historical benchmarks, *etc.*), and storytelling.

The inspiration-exploration phase is aimed at identifying problems and expectations. This is a phase where the team gathers information from different sources. The field favors the multiplication of ideas, the appropriation of the problem by the team, and thus the development of the motivation and the empathy within the team. The mastery of ethnographic research is essential for understanding the context of use and users and therefore the generation of ideas and solutions. Ethnographic research is crucial in the overall approach of the DT process, both in defining the needs and in designing relevant and creative solutions. DT relies on several tools (interviews, photos, videos, *etc.*) in order to enable teams to immerse themselves in the user experience in context as well as to collect perceptions at different stages of the project.

During the “conceptualization” or implementation phase, teams are encouraged to quickly test the first solutions envisaged using rudimentary prototypes in order to demonstrate their relevance. Investing directly in sophisticated prototypes presents the risk of leading them quickly on the convergence process and therefore not exploring all options. This highly experimental approach, by which the project is refined, co-developed through successive confrontations with the field and the user’s expectations, reduces the likelihood of disillusion that a team can experience at later stage of the project. Before the final prototype, the teams have the possibility to use different prototyping tools according to the stages of the project: drawing, cardboard, digital mock-up, and 3D printing. The main objective of the various prototypes, whatever their nature, is to collect feedback from the users regarding the relevance of the imagined solution(s) to be able to improve the prototypes in an iterative way.

Because of the strong orientation towards concrete action, fast or even temporary solutions, some researchers consider that it would be better to speak of “design-doing” instead of design thinking. This bias towards action can lead to the

implementation of a technical solution without really taking the time to engage in a genuine reflection about the root causes of the problem to be solved.

Design Thinking Challenges and Limitations

As described in recent review (Bourgeois-Bougrine et al. 2018), DT has been the subject of much criticism from researchers and practitioners. A frequent comment made about design thinking is the lack of a theoretical basis and academic rigor. Johansson-Sköldberg et al. (2013) suggest that these issues are due to two design thinking discourses: the academic discourses of “design(erly) thinking” and the management discourse. “Designerly thinking” refers to the academic construction of the professional designer’s practice, links theory and practice from a design perspective, and is accordingly rooted in the academic field of design. Within the managerial realm, “Design thinking” becomes a simplified version of “designerly thinking” or a way of describing a designer’s methods that is integrated into an academic or practical management discourse. In general, it has a more superficial and popular character and is less academically anchored than the designerly one (Johansson-Sköldberg et al. 2013, p. 121).

Many of DT’s influential ideas were, indeed, introduced in the 1950s by a Stanford educator, John E. Arnold, and his successors at the Mechanical Engineering department (Leifer and Meinel 2019). Arnold’s creative theories, such as creative engineering theory, need-based design theory, visual thinking, ambidextrous thinking, *etc.*, were inspired by McKim, Paul Guilford, and Abraham Maslow, as well as the philosopher Robert Hartman and the architect Buckminster Fuller (von Thienen et al. 2018). Further theoretical perspectives were introduced between the 1970s and 1990s with the foundational works of Simon, the Nobel Prize winner, and Schön, Buchanan, Lawson, and Krippendorff, among others (for extensive presentation see Johansson-Sköldberg et al. 2013).

Another major critique of DT is that radical innovations do not come from human- or user-centered approaches. Empathy towards users makes it possible to understand their needs and results in an incremental improvement of what already exists or in the development of a product or service to satisfy those needs. In an interview, Clayton Christensen, who developed the theory of “disruptive innovation,” considered that

the problem is when you say ‘listen to your customers,’ your customers are only going to lead you in a direction that they want to go in. Generally, that will never lead you to disruptive growth. You’ve got to find that new set of customers, and listen to them and follow them. That’s the trick. Once you have customers, they hold you captive to their needs [...]. You have to be careful which customers you listen to, and then you need to watch what they do, not listen to what they say”. (McGregor 2007 in Bourgeois-Bougrine et al. 2018).

Another challenge is related to the fact that engineers and managers perceive user insight as unspecific when it is not directly translated into technical requirements. In addition, insight gained and the reformulation of the initial problem may result in ideas and concepts that are difficult to implement if they are outside the scope of the company’s product planning. The iterative and explorative approach of DT is resource intensive and clashes with “the linear, efficiency-oriented processes of incremental product development” (Carlgren et al. 2016, p. 347 in Bourgeois-Bougrine et al. 2018). In addition, other cultural elements of DT, such as having fun, testing hypotheses quickly, interacting with users, failing and learning from mistakes, are perceived as challenging for companies with a strong risk-averse culture. Often reinforced by national cultures.

The Possible in Design Thinking

Promoting Radical Innovation: Enhancing DT

Radical innovation is only possible if a company overcomes the internal and external innovation barriers, breaks out from old mindsets, and unlearns existing routines and old logic (Assink 2006). The hill-climbing

paradigm¹ applied to incremental and radical innovation suggests that incremental innovation attempts to reach the highest point on the current hill, whereas radical innovation seeks the highest hill (Norman and Verganti 2012). Radical innovation implies a break with the past, either through the introduction of a new technology, a paradigm shift, or through a new vision that comes from a deep reinterpretation of the meaning of a product or service in line with socio-cultural changes. Users have difficulty anticipating their needs or considering this reinterpretation because of their total immersion in the current context and in the cultural paradigm. Iskander (2018) argues that DT is fundamentally conservative, unsuited to uncertainty, and preserves the political, economic, and physical status quo – all at odds with different possible futures of a product, service, company, or culture, more broadly.

Drawing on the benefits of prospective ergonomics and virtual environment, Bourgeois-Bougrine et al. (2017) proposed a combined approach to enhance DT in order to promote radical innovation mindset and open up the field of the possible within DT. Prospective ergonomics aims at “anticipating future needs, uses and behaviours or building future needs in order to create processes, products or services adapted to them” (Brangier et al. 2017, p. 48). Prospective ergonomics does not intend to predict the future or to reveal it as if it were something that already exists (de Jouvenel 2002), but rather invites it to be constructed. This approach uses rigorous methods that are quantitative, qualitative, normative, or exploratory in nature (Gordon and Glenn 2004): agent modeling, bibliometrics, causal layered analysis, decision modeling, *Delphi* techniques, scenarios, morphological analysis, road mapping, text mining, trend impact analysis, future wheel, and more.

¹Hill climbing is a mathematical optimization technique that attempts to find a better solution by incrementally changing a single element of the solution. If the change produces a better solution, an incremental change is made to the new solution, repeating until no further improvements can be found (Wikipedia: The Free Encyclopedia 2018).

With the aim to promote ideation and empathy, the proposed approach takes as a starting point the imagination of future needs using prospective scenarios approach, instead of users' latent and unmet needs (Bourgeois-Bougrine et al. 2018). This combined approach involves both analytical and intuitive thinking, imagination and creativity, as well as collaboration and communication within multidisciplinary teams that are involved in the development of artifacts and services that would change social practices. Once an innovative and futuristic challenge is chosen, teams enter a new cycle of the DT process according to the above-mentioned five-step model: empathize, define, ideate, prototype, test.

Moreover, recent research has shown that Multi-User Virtual Environments (MUVE) hold the potential for greater creativity support due to behavioral modulation in situations of physical isolation, the anonymity of the users, and the avatar appearance. MUVE allows for an exchange of ideas without production getting blocked when ideation tasks are held in virtual environments. "Productivity loss" has been reported in brainstorming groups. This has been linked to social inhibition due to evaluation apprehension, the impossibility to say two ideas aloud at the same time (production blocking), the tendency to suggest ideas too similar to others (fixation), and the tendency to rely on the group to suggest ideas (social loafing). It has been suggested that MUVE represents a conducive, safe, and comfortable environment that can elicit global processing and exploration, because, in this kind of atmosphere, individuals are more eager to take risks and that the perceived freedom from constraints triggers a risky, explorative processing style that promotes creativity.

In addition, virtual reality promotes empathy-related phenomena such as perspective-taking, which is the cognitive ability of imagining the perspective of others, to understand the experiences, the feelings, and emotions of others and show compassion and altruism. Virtual reality allows individuals to step into someone else's shoes, through a perceptual illusion called embodiment or body ownership and to move their perspectives to different scenarios and

universes. Therefore, virtual environments should be more explored in terms of the embodiment of various possible personas to foster empathy and co-creativity when involving users.

DT and Human-Centered Design

Because it places higher priority on human needs, DT is considered a human-centered approach to innovation. However, Human-Centered Design (HCD) definition and requirements depend on the context. For instance, IDEO, the company that made DT popular, defines HCD as a creative approach to problem-solving that cultivates a deep empathy with the target people you are designing for. In the domain of computer-based interactive systems,² HCD aims to make systems usable and useful by focusing on the users, their needs and requirements, and by applying Human Factors/Ergonomics,³ and usability knowledge and techniques. This approach enhances effectiveness and efficiency, improves human well-being, user satisfaction, accessibility, and sustainability, and counteracts possible adverse effects of use on human health, safety, and performance. This definition highlights the utility of HCD as an extension of Human Factors/Ergonomics (Kasdaglis and Stowers 2016 p. 345). Human Factors/Ergonomics is considered as a science-based discipline that brings together knowledge about human abilities and limitations from other subjects such as anatomy, physiology, psychology and uses it "to design systems, organizations, jobs, machines, tools, and consumer products for safe, efficient, and comfortable human use."⁴

Despite the fact that DT is considered to be a HCD path to innovation, it does not explicitly

²Computer-based interactive systems vary in scale and complexity and examples include automated banking systems, Web sites and applications, vending machines, mobile phones and digital television, etc.,

³The expression human factors is a predominantly North American. The terms 'ergonomics' and 'human factors' which can be used interchangeably are concerned with "fitting a job to a person" to fulfill the goals of occupational health and safety and productivity.

⁴<https://osha.oregon.gov/edu/grants/wrd/cergos/Pages/ergonomics.aspx>

spell out the Human Factors line of investigation as one of its core values. In the context of industrial or computer engineering, DT practitioners should be made aware of and use Human Factors/Ergonomics approaches and recommendations throughout the DT stages. As Endsley and Jones indicate, HCD does not mean “*asking users what they want and then giving it to them*” (2011, p.7). In the context of complex system, HCD means that (a) the technology should be organized around the “way users process information and make decisions” and (b) keep the user in control and aware of the state of the system (Endsley and Jones 2011, p.11). The integration of HCD and DT cultivates new directions in the possible for complex systems and design in response to current and potential human needs.

Possible Design Thinking Uses: Life Design

According to Burnett and Evans (2016), by applying the principles of DT, it is possible to better design and build a meaningful life. They use scientific data from positive psychology and neuroscience to support their claim. The approach adopted by Burnett and Evans supports the idea that career development should go beyond looking for a job. For this, they propose an approach based on the principle that an individual can think like a designer and build or design not only a career, but also their life. As the economic and social environments change rapidly, it is important to adopt the curious attitude of a designer and to have a bias for action to quickly imagine, design, and test new alternatives. According to these authors, when the individual wishes to imagine possible futures, there is no reason to be skeptical because no one knows what the future would look like. This notion relates to Zittoun and de Saint-Laurent (2015) idea that the possible in self-actualization can be thought of as *life-creativity*. Burnett and Evans suggest starting with adopting curiosity as a state of mind instead of skepticism to be more generative. In addition, as the future is uncertain and one cannot plan for what is unknown, the authors consider that the best way to design one’s life is to have a bias for action. Taking action consists in “making prototypes” and testing them quickly to make sure that reality matches to the

idea that one has. They like to say that no life plan survives the first contact with reality.

The life design process includes the five stages of DT with an additional stage called “acceptance.” In fact, the first step is to agree to participate in a life design workshop because more often than not people complain about their work, hate their boss or don’t like their life but do nothing to remedy it. Accepting therefore means that we are interested and motivated to find solutions. They also describe several tools that can be used to help participants build a life worth living such as the dashboard, the moral compass, the good time journal, AEIOU (for Activities, Environments, Interactions, Objects, Users), odyssey planning, immunity from failure, mind-mapping, and more.

In the context of life design, empathy consists of understanding yourself and identifying your worldview (lifecycle) and workview, as well as the adequacy between these two visions. The alignment of these two visions gives the individual a “moral compass” and allows the person to refer to it. As design thinking is known for its ideation phase, life design uses several tools to create different alternatives of the future, such as the Good Time Journal and Odyssey planning. The prototype/test cycle is about prototyping experiences to discover more about a job, to feel what it would be like to be a writer, for example. Burnett and Evans (2016) like to say that prototypes are a way of sneaking up on the future. In this way, DT provides a well-articulated approach to imagining and planning toward possible future identities and pathways for the self.

Conclusion

According to Don Norman (2013, p.219), “design thinking is not an exclusive property of designers – all great innovators have practiced this approach, even if unknowingly, regardless of whether they were artists or poets, writers or scientists, engineers or business people. But because designers pride themselves on their ability to innovate in finding creative solutions to fundamental problems, design thinking has become the hallmark of the modern design firm.”

Some researchers highlight several challenges that are related to the main core themes of DT, for example, user focus, problem framing, and iteration. In the past few years, users have been increasingly involved in the development of new products. This is mainly motivated by the idea that users have knowledge of their own needs and are able to develop solutions that fit those needs. The challenges and limitations at both individual and organizational levels in implementing DT entail a need to develop the ability to discard out-dated mental models and to adopt radical innovation mindset. As Daniel H. Pink (2006, p.2) considers “the future belongs to a very different kind of person with a very different kind of mind – creators and empathizers, pattern recognizers, and meaning makers.” To benefit from DT, one needs to think and act like a designer to a certain extent and not “forget that people don’t buy just utility. People buy meaning and emotion and symbols” (Verganti 2010). In considering DT as a pathway in the field of the possible, that notion doesn’t relate just to goods and services but also to the life course we invest in every day.

Determinism · Prediction · LaPlace · Possibilities · Future · Free will

Definition

Determinism is the theory that all events in the universe are completely caused by prior events, such that every occurrence was inevitable from the start of the universe, ranging from the intricate blast of every supernova, to the precise path each leaf travels as it flutters to the ground, to the very words we are writing in this entry. It is a brilliant, elegant, controversial, and challenging theory. Philosophers and scientists disagree profoundly about whether determinism is true and whether it applies to human behavior. Given the controversial nature, we stipulate our own views at the outset. The first author (RFB) was a determinist for many years but eventually defected, so he now disbelieves in determinism. The second author

(CJC) believes all occurrences are caused by prior events, but that randomness likely interferes with inevitability or the possibility of perfect prediction of future outcomes (e.g., Clark 2020). The third (SL) thinks that strict determinism is a powerful methodological tool to reduce uncertainty because it creates inevitabilities by assuming them for *any* relationship between events. However, this tool is also an idealistic doctrine from the view of psychology, as psychological science did in reality choose a different path, creating a successful methodology that is essentially incompatible with the demands of strict determinism.

Determinism is included in this Encyclopedia because it has profound implications for the notion of possibility. Readers wishing a longer, more philosophically sophisticated treatment of the topic may consult Hoefer (2016). In its strictest form, determinism denies that anything is truly possible that does not actually happen. Individuals facing a choice may think that two or more options are truly possible, but they are mistaken, according to determinists. What people end up choosing was the only possible option they could have chosen, and this was determined long before they were born. Their (false) belief in alternative possibilities is however a legitimate part of the causal chain leading to the decision.

Deterministic theories have been developed in many cultural and conceptual contexts. Nevertheless, the definitive and most influential statement was made by Pierre-Simon LaPlace (1814/1951) in the early 1800s. He was a statistician, which is ironic because determinism undercuts one of the key assumptions of probability theory, namely that multiple outcomes are possible from the same situation. LaPlace is important for having formulated a scientific form of determinism, but there were certainly religious and philosophical versions that preceded it. The Calvinist doctrine of predestination is quite similar: God knows everything and therefore already knows everything that will happen in the future – so you can only act out what is inevitable rather than changing or choosing anything.

LaPlace observed that in principle it would be possible for a highly intelligent supermind to calculate every future event with complete accuracy if it possessed a complete knowledge of the

disposition of every particle in the universe at present plus a complete knowledge of the laws of nature. (The supermind was not meant to invoke a god; today, one would imagine this as a computer, but of course LaPlace died long before computers were invented.) Indeed, if one could possess such complete knowledge of the arrangement of particles at any given point in time, plus a full and correct knowledge of all causal principles, one could unerringly calculate the state of the universe down to every particular detail at every point in the future or the past. Sometimes, this is formulated as treating the universe as a giant machine, grinding along exactly as programmed, one moment after another. Everything that happens today was inevitable since the origin of the universe, or possibly a few seconds thereafter. As Hoefer (2016) explains it, a supersmart demon who knew the full state of the universe a hundred years before your birth would be able to predict unerringly every moment of your life, including all your thoughts, feelings, and actions. Hoefer explains further that this is why determinism infuriates some people and gives perverse satisfaction to others, because it depicts the human being as a marionette or puppet, pulled about by external causes without any real say in the matter.

LaPlace surely did not think such calculations would be made any time soon, in practice. In fact, recent calculations suggest the universe could not contain enough computing power to make those calculations (Wolpert 2008). The implication of LaPlace's idea is not that people will soon be predicting the future with complete accuracy, but that it would be theoretically possible with the right data and equipment. The profound implication is that there is only one possible future. The assumption that there is a single correct answer requires that every future event be inevitable. If multiple future outcomes were possible, the supermind could not possibly calculate with completely confident accuracy which one will become real. Thus, ultimately, the category of what is possible is the same as what actually happens.

The illusion of multiple possibilities is an important feature of determinism. If everything in the future is already determined, then the

human sense that one could choose between multiple actions is illusory by necessity. Determinists emphasize *epistemic possibilities*, defined as possible in terms of thinking, but not possible in physical reality. That is, a person might believe subjectively that multiple possibilities exist, and the person's belief in multiple possibilities might have a genuine causal influence on the person's behavior. There is no genuine reality of mere possibility in the physical sense, but there is a subjective (and illusory) belief in multiple possibilities, which is part of the deterministic causal chain. For example, tonight you lock your home's doors to prevent criminals from entering to burglarize and terrorize your family. In reality, the criminals do not break in tonight, and that outcome was inevitable long before you were born. But your mistaken belief that such an invasion was possible caused you to lock your doors. One can think that even if you had not locked the door, you still would not have been burglarized. Nevertheless, it has been inevitable for many centuries that tonight you will lock the door and that no criminals will invade your house.

Determinists also accept that unrealized physical possibilities can be contemplated – but only based on the assumption that the entire history of the universe were different, dating back to its origin with the Big Bang. They acknowledge that people can have thoughts of the form that “If X were not true or had not happened, then Y would not be true or would not have happened.” For example, if Sam had not left his ice cream sitting out in the sun while he went indoors for a long phone call, then it would not have melted. Of course, given the reality of our universe, it was inevitable that Sam would leave it sitting there, and nothing else was possible.

Appeal of Determinism

Determinism appeals to many thinkers for multiple reasons. (For a passionate modern assertion of determinism in social psychology, see Miles 2013; note critical response by Vonasch and Baumeister 2013.) First, it is a highly elegant theory. It assumes that causes lead inevitably to

their consequences. This assumption is consistent with observations in some of the simplest experiments. For example, if a scientist mixes two substances in precise proportions in a sterile test tube, particular reactions are highly predictable. Once someone accepts the premises of determinism, which are deceptively uncontroversial, there is almost no way to avoid their sweeping conclusions. Determinists propose that the laws of nature would have to be overturned in order for their vision of the world to be refuted.

A second aspect of the appeal of determinism is that it runs counter to everyday and naïve intuitions. It thus holds out the promise of freeing people from huge illusions. (Or, even if people cling to their illusions, determinists are able to feel superior to them based on supposedly knowing something that others do not.) People may think they make choices in an environment that genuinely contains multiple possible alternative illusions – but they are at least partly mistaken, according to determinists. What they end up choosing was always the only option they could ever have really chosen. Their subjective impression that they could go either way is mistaken. Thus, determinism is appealing because it enables believers to think that everyone else is mistaken many times every day in the belief that the future contains multiple alternative possibilities. In a simple example, the restaurant patron scans the menu and subjectively but mistakenly believes that all these options are possible, and he or she merely must decide which of these options is the one to choose. One could choose the beef, or the chicken, or the fish. In reality, to a determinist, it was unequivocally determined long back before 1800 that today you would select the chicken, and the possibility of selecting fish or beef was an illusion.

Third, determinism may be appealing because it appears to reduce uncertainty. In a deterministic world, it would be theoretically possible to learn all of the causes in the universe, how they will interact, and what the future holds. Human behavior and future outcomes are theoretically predictable and explainable. The appeal of determinism may be much like the appeal of a psychic: It appears to reduce uncertainty about the future.

Indeed, Baumeister and Lau (2021) found that junior psychological scientists tended to endorse determinism more than senior scientists. Uncertainty is an ubiquitous and critical adaptive challenge (e.g., Hirsh et al. 2012), and likely very prevalent in a taxing context like starting a scientific career. We therefore suppose that stronger beliefs in determinism might be just that – an adaptive mechanism that helps to cope with uncertainty in an already overcomplex context.

Alternative to Determinism

The alternative to determinism is the reality of mere possibility: that some things are genuinely possible at one time but in the long run will never become reality. For this *Encyclopedia of Possibility*, the alternative is especially important. To determinists, alternative possibilities are illusory (though they may enter into the causal chain: Someone might mistakenly believe that something is possible and on that basis take steps to prevent it). Yet the mistaken belief in alternative possibilities is a legitimate and genuine part of the causal process.

Determinism denies the reality of mere possibility, because that reality would imply that the causal processes in the universe do not fully determine the future, instead leaving open multiple alternative outcomes as possible. The opposite of determinism may be the multimaybe matrix (see separate entry), which treats the future as a set of alternative possibilities, each of which may or may not come true (Baumeister et al. 2018).

A world governed by probabilities would be incompatible with determinism. In particular, determinism sees causes as ensuring their effects, with no exceptions (unless overridden by other causes). In contrast, many social scientists believe that many causes are probabilistic. That is, a cause does not produce an effect but merely changes the odds of its happening. Such analyses do not fit well with Newtonian physics, but nearly all the causes described in psychology, economics, and indeed all the social sciences appear to operate probabilistically. The determinist could argue, however, that this appearance of probabilistic causation comes from the complexity of

psychological events, which can be affected by many different causes. In other words, probabilities are only useful in the social and behavioral sciences because we have not identified or do not have the right tools to measure all of the causes, and so models are imperfect. If we did know all the causes and have the right tools, probabilities would cease to be useful (all outcomes would either be 0% likely or 100% likely).

The deterministic doctrine that probabilities and statistics merely reflect human ignorance rather than objective reality shows the way to one possible test. Over time, the progress of science has reduced human ignorance considerably and should continue to do so. As a result, the use of statistics in science should diminish over time. It should therefore be possible to study long-term trends in scientific methodology to ascertain whether use of statistics steadily decreases (as determinists would predict), remains the same, or increases.

Relevance to Free Will

Determinism has been of particular interest to philosophers in relation to free will. Free will is often defined in terms of the ability for the individual to act differently in the same situation, thereby potentially leading to different future outcomes – precisely in contradiction to determinism, which holds that only one future course is possible. In psychology, determinism takes the form of asserting that a person's behavior in a given situation is an ineluctable outcome of the person's genes and environmental influences (e.g., reinforcement history). Thus, although the person has the subjective impression that he or she could act in different ways, that is an illusion. What you do is inevitable and indeed has been for a long time, according to determinism.

Elaborate reasoning has found ways around that seeming contradiction. The majority of philosophers today believe that free will is compatible with determinism. They treat free will as part of the chain of causal processes that produce the predetermined result. People may be mistaken in believing that they are capable of making various

alternative choices, but that mistaken belief is a vital part of the deterministic causation of what will inevitably happen. And to some scholars, that level of agency warrants the term “free will.”

Nevertheless, people who have not read deeply in philosophy continue to regard determinism and free will as incompatible (rejecting determinism and upholding free will; Clark et al. 2019). The simple intuition is that determinism rules out free will. If free will means being able to act differently in the same situation, this contradicts the deterministic assertion that one could not act differently in that situation.

Survey Results: What Do Psychologists Believe?

A survey of psychologists' beliefs was conducted by Baumeister and Lau (2021, under review). The survey was offered to the entire membership of the Society of Personality and Social Psychology, and responses were recorded for all who volunteered. Admittedly, the sample who furnished data may not be representative of the scientific community as a whole, especially if people who hold one view are more likely than their opponents to agree to complete the survey.

Briefly summarized, we found a wide range of opinion among social/personality psychology faculty and graduate students. Younger researchers were more sympathetic to determinism than older ones. Most opinions were tentative, and the most intermediate response was the most popular. For example, 23.7% of the sample reported being completely undecided (the midpoint on an 11-point scale) about the statement that “determinism is true.” Thus, many psychologists do not have strong opinions on the topic, but some do, and there is no consensus.

Criticism of Determinism

Some of us have written sharp criticism of determinism from a psychological-science standpoint (Baumeister and Lau 2021). We acknowledge the philosophers have refined their views to a very

advanced level, but our concerns are somewhat different.

Our main point is that determinism is badly unsuitable as a conceptual basis for (social and other) psychological theories. The central point of determinism is inevitability: In each situation, only one outcome is possible. In sharp contrast, most of the phenomena studied by human person-focused psychologists are essentially based on situations having multiple possible outcomes. For example, psychologists study threat: A threat is something bad that might happen but also might not happen. Similarly, success is only meaningful if failure were possible. Negotiation and compromise can only occur under conditions in which there are multiple possible outcomes. The list goes on and on.

The point is that determinism blinds researchers to the key thing they seek to explain, namely how agents respond to situations defined by multiple possible outcomes. One can delineate a theory about how the agent processes information, interacts with others, and responds to changes in the situation. Researchers can then collect data to test and refine their theory. Then along comes the determinist to say that the final outcome was always inevitable anyway. That is not at all helpful to the theory. Although determinism perhaps cannot be ruled out definitively, its adoption would hinder more than it would help prediction models in the social and behavioral sciences. And where a theory leads to worse predictions, it seems reasonable to question its accuracy.

We speculate that this may be why psychology does not seem to have any genuinely deterministic theories. Most theories invoke multiple possibilities. In parallel, the overwhelming majority of psychological studies merely show a small change in the odds of one response as opposed to the alternative – rather than finding that a cause guarantees its effect. Although a substantial minority of psychologists profess to believe in determinism, it is neither evident in their theorizing nor in their own data.

We also humbly suggested that determinism has two fatal flaws as a viable modern psychological theory anyway. First, the thought experiment

itself could not be done, because it violates relativity theory. LaPlace assumed you could have a single moment of the entire universe, as if it were in some context exactly the same time at every point in the universe. Of course, that was plausible back when LaPlace lived, during the French Revolution and Napoleonic period. Relativity theory did not appear for another century.

The other is that determinism ends up being circular reasoning. This becomes relevant if one can get past the problem of relativity. If there is for effective practice a single simultaneous moment for the entire universe, and the supermind had all that information, it would also need to know not only all the individual causal laws but also how these causes combine and interact, because some causes can override or alter the impact of others. The knowledge of causal laws would have to include what happens with each possible combination of causes. Because each moment of the universe is effectively unique, it presents a unique combination of causes. Therefore, the supermind would have to know what happens with precisely the layout of the universe at each moment. In essence, it would be predicting what happens next from the present moment based on its knowledge of what happens in a moment exactly like the present moment. That makes the reasoning circular: Based on knowing A, it can predict A.

Summary/Conclusion

Determinism asserts a very limited view of what is possible. It emphasizes that the future course of physical reality is inevitable and has been determined in advance for a very long time. It accepts the notion of epistemic possibility, that is to say, determinists know that people can imagine alternative possibilities – but nothing was ever truly, physically possible other than what actually happens.

Dialectics

José Antonio Castorina

Universidad Pedagógica Nacional, Universidad de Buenos Aires, CONICET (Consejo Nacional de Investigaciones Científicas y Tecnológicas), Buenos Aires, Argentina

Abstract

This entry aims to examine the features of dialectics when studied from the perspective of the psychological development of knowledge and its functions in the works of Piaget, Vygotsky, and Valsiner, where it is described as a novelty producing process. In these authors,

dialectics is understood both as a research methodology and as a constitutive part of the explanation of psychological development. In Piaget, the dynamics of dialectics and the possible are examined through the equilibrium theory of development, which includes dialectical inferences specific for epistemic constructivism and based on the interplay between undifferentiation, differentiation and integration. In Vygotsky, interpreting the dialectics of possible novelties in higher mental functions, particularly the zone of proximal development can be seen as a dialectical reorganization achieved through guided development, from a learner's real knowledge to what she can achieve with others' assistance, i.e., an actualization of potential knowledge. In Valsiner, the synthesis of opposites is the main feature of dialectical thinking, hence the “actual” is a construction from possibilities allowed by an earlier level of development in the interaction between an individual and their own semiotic world. It is argued that each author contributes to understanding the relations between the possible and actual, especially given the difficulties faced by each approach, and they all pave the way for new research questions.

Keywords

Dialectic · Development novelty · Dialectical inference · Synthesis · Possible · Actualization

In the history of philosophy, there is no single way of describing dialectical thinking, though the question has been addressed by philosophers ranging from Heraclitus and Plato to Hegel and the *Naturphilosophie*, continuing with Marx and different schools of Marxism, including Della Volpe and Sartre. More recent examples include Jameson and the philosophy of science of Bachelard, Bashkar, and Lewontin, among others. Dialectics has also been subjected to diverse critiques by figures like Foucault and Deleuze and certain analytic philosophers (Gadamer 2000; Jameson 2013; Harvey et al. 1996; Popper 1972).

Instead of contributing to this particular discussion, the aim here is to describe the different qualities of dialectics when used in the field of psychological knowledge, including studies on development, natural logic, semiotic systems, and psychological functions. In addition, the focus is on how the possible constitutes these systems of thought regarding its dialectics features. In this regard, highly influential authors in the field such as Vygotsky (see chapter ► [“The Possible in the Life and Work of Lev Vygotsky”](#)), Piaget, and Valsiner have used dialectics to guide their methodology and explain the process of development. Piaget and Valsiner, in fact, included an explicit analysis of the category. The qualities attributed to dialectics in this area are highly dependent on the problems addressed, the objects constructed in each field of phenomena, and the procedures used in the scientific investigation. In any case, the use of dialectics does not constitute a plain and simple *a priori* “application” of philosophical theses, nor does it take a single form. In fact, dialectics depends on the interplay between observable phenomena, methods, and theories in the methodology cycle of research (Valsiner 2012a, b). As an epistemic framework, it offers a broad context for specific ways to pose problems, produce investigations, and specify the processes of transformation in development.

In the context of this entry, the focus will be on how dialectical thinking is particularly well suited for examining the emergence of novelties, the main issue of development yet to be resolved. Aristotle (Ross 1964) was the first to make the distinction between the possible (or potential) and the actual, the two inseparable dimensions of all human action, because an act becomes effective when a potential is actualized. If activity is considered a development, these two dimensions are inextricable. While the act situates it in the realm of the real it, at the same time, invokes a set of possibilities that give our development depth. When considering the contingent character of the act in development, it also becomes necessary to examine it retrospectively. According to the authors mentioned, developmental psychology explores the potential for qualitative change in

development of and for the construction of new identities, concepts or functions. In other words, these thinkers research the processes of actualizing potential and even address the possible itself.

The Dialectical Perspective in Developmental Psychology

In essence, this entry proposes the hypothesis that there are “axiomatic” assumptions (Valsiner 2012a; Overton 2012; Castorina 2007) that intervene in the methodology cycle of psychological research, placing limits on the problems that researchers can and cannot consider. Mainstream research in psychology has been dominated by two different sets of assumptions. The first are ontological assumptions about the separation between the individual and the social and nature versus culture. The second are epistemological assumptions that split the theory of experience, or the meanings of behavior, or the values of facts. This epistemological framework has guided research, particularly that of neoinnatism, cognitivism, behaviorism, and, on occasion, contextualism (Overton 1998). Although it has not determined the outcome of investigations, it has conditioned them, and, on occasion, has prevented issues related to transformation processes from being discussed. This has forced researchers to investigate “the beginning of knowledge” due to believing in innate processes, or obliged them to treat individuals or behaviors as the main unit of analysis. It has also led to the deification of the “methods” of positivism and even the elimination of evidence “of the dynamic flow of the phenomena in research data” (Valsiner 2012a, b).

On the contrary, in works on developmental psychology by Piaget and Vygotsky, the components of experience are dynamically integrated with the world. This can also be seen in the socio-historical school of psychology and in cultural psychology (Valsiner 1997, 2006, 2012a, b). This focus, though still rare in developmental psychology (Valsiner 2012a), converges with the perspective of the contemporary sciences centered on open systems, which are characterized by symbolic or informational exchanges with their

particular medium (Overton 1998). Thus, it is postulated that a process of qualitative change would yield novelties in the processes under investigation, for example, systems of knowledge or psychological functions. In addition, what changes in a system are the relations between elements that make up a totality, for example, those which connect culture and intellectual activity. The source of the change here resides in the interactions inherent to the system, thus affirming their self-movement, and the contradictions are what provoke the creation of novelties (Bidell 1988).

This is a thinking strategy that makes dialectical interactions necessary, depending also on the specific focus, in developmental systems. On the one hand, this strategy is a relevant component of the methodology cycle during research that allows for a theory to be elaborated; on the other, dialectical processes are laid out as a crucial part of an explanatory theory of the production of novelties in social and psychological systems. In short, besides proving compatible with empirical investigations, dialectics is a valid tool to advance knowledge on the transformations of psychological systems and also to explain processes of change.

Piaget

Dialectics is, first and foremost, a methodology, as whenever Piaget addressed an issue related to development he included heterogeneity – and oftentimes, the opposition between the predicted properties – seeking to integrate them in the reconstruction of the dynamics of knowledge formation. Thus, for example, the notions of assimilation and accommodation can only be thought of in relation to one another (as occurs with schemata and observable phenomena; presentative and procedural schemata; subject and object) and must be considered as a dynamic unit, recognizing intrinsic oppositions, which are emphasized during the actual genesis of knowledge.

Second, the systematic use of this approach is “achieved” in Piagetian psychological theory since the object of the research incorporates a

dialectical process. In other words, in order to elaborate the specific issues surrounding the emergence of novelties in the formation of logical systems, it is necessary to recognize the dialectical processes at work within development psychology. In this regard, unlike logical contradictions, natural contradictions arise from questions posed by the subject which she is unable to resolve beforehand. For example, a child who attempts to explain how to balance a sliding scale thinks about the weight factor separately and is struck by the contradiction. For the child sitting before the scale, a single action can cause different effects since, when weight is added to one side, that side will generally go down but not always, depending on the amount of weight on the other side, and the distance of each weight from the fulcrum. In other cases, an action and counteraction do not compensate for one another: when weights are added to a pan that already has other weights in it, it will go down, but the same may also occur if these weights are removed. In general, the inability to think of how the physical properties relate to one another causes these contradictions. Later, the child comes to interpret the problem in terms of not only weight but each weight’s distance from the fulcrum, also referred to as its moment. As this occurs, her understanding of the concept is progressively relativized and her point of reference expands. Therefore, a heavier weight at a shorter distance can be offset by a lighter weight farther from the fulcrum (Piaget 1974).

However, these contradictions – from the perspective of constructivist epistemology – provoke but do not produce cognitive development (see chapter ► “Possible in Human Development”). They are merely an instance within a broader process of equilibration in knowledge systems. The reorganization of these systems can be explained, first and foremost, by “desequilibration” between affirmations and negations that provoke conflict. A re-equilibration later becomes necessary on the part of the subject, who must offset the affirmations with the negations through “reflecting abstractions,” constructive generalizations and the invention of new possibilities (Piaget 2001, 1984; Campbell 2009). Contradictions are part of a joint

process that requires constructive mechanisms in order to produce cognitive “novelty.”

In one of his last works, *Les formes elementaires de la dialectique* (1981), Piaget reconsiders dialectics in an original way, approaching it as a (non-deductive) inference that leads from a conceptual system to another, a more advanced one, which cannot be reduced to its prior state. Thanks to this “inferential side of equilibration,” which corresponds to the systemic interaction that yields the cognitive novelty, one level of attributing meaning is transformed into another. These inferences can range from undifferentiation to differentiation and conceptual integration, the articulation of primarily independent knowledge systems, the constructivist modification in subject-object interactions, and proactive and retroactive inferences in knowledge.

Thus, in terms of the types of inferences, the processes of undifferentiation, differentiation and integration are perhaps the most relevant to the study of the genesis of knowledge. A small child looking onto a mountain range imagines that if she were on the other side, it would look exactly the same. In other words, she is unable to differentiate between perspectives and only becomes able to do so when she progressively builds an operational system of perspectives that allows her to consider simultaneously the reciprocal relations at work. It is thus possible to speak of an inferential process that moves from the undifferentiation of properties to the differentiation and integration of perspectives.

In summary, the framework of dialectics has guided research in developmental science, serving as an assumption within the methodology cycle and as a central component of the theory of equilibration. The “inferential side” of dialectics, which reveals the construction of cognitive novelties, has been emphasized in psychology theory. In his approach to equilibration, Piaget suggests that certain “novel” states of knowledge surpass prior states.

The Possible as a Construction

According to Piaget, in order to overcome empiricism and epistemic innatism, it is necessary to explain “novelty construction” (see chapter “► Novelty”) through the theory of equilibration

between assimilation and accommodation, in the interaction of subject and objects. Yet this construction can also be considered in terms of the elaboration of that which does not yet exist in the virtual state “of the possible” that the subject must actualize. To the detriment of empiricism, Piaget affirms that the possible cannot be observed; it is, instead, the product elaborated by the subject as she interacts with the objects. In this regard, the possible is not static and things “become possible” (Piaget 1976) when they reach the moment in which they can be actualized. In terms of innatism, Piaget affirms that the possible does not precede the moment in which actualization occurs, as in the possible is not given beforehand, but it is a byproduct of becoming a psychological subject. They are not predetermined, as shown in studies revealing the qualitative changes that occur in formulating the possible among children aged four to twelve. Without a doubt, what underlies these studies is the idea that “the set of all possibles” is an antinomy given that “all” is a possibility impossible to define since it is ceaselessly increasing (Piaget 1976). The only option is to consider the possibilities that can be inferred from an operational system, that is, the possible perspectives that can be conceived from a structure of spatial perspectives, seen earlier. Yet it is the subject who elaborates the possibles, or to put it bluntly, the new possibles. From the constructivist point of view, possibility unfolds as the subjects’ action is in its course, outside this realm, there is little point in discussing “the possible.”

Studies have addressed how subjects can find the greatest number of variations in an action, for example, finding all the ways possible to cut out a square; arranging blocks so as to have a better view of one side; or building a geometrical figure like a triangle in different ways (Piaget 1981). While small children can only imagine a limited number of variations, older children may go so far as to claim that there is an “infinity” of variations. Now, how can this multiplication of the possibilities be explained? The answer lies in distinguishing the presentative schemes (schemes generalized in different contexts), which deal with the simultaneous and articulated characteristics of objects, like the concepts in a classification. They

stand apart from contexts and procedural schemata, which are context-dependent and consist of the means applied towards a goal, for example, to solve problems and attain success in this realization. The opening of new possibles depends almost entirely on the application of these schemata, in the belief that good results can be achieved, though there are also errors (unforeseen or undesirable outcomes from action) between the possibles, which allows the unpredictable and incalculable.

In terms of dialectical processes, the inferences children make range from undifferentiation to differentiation and the integration of the possible, the necessary (understood as a process of deduction carried out by the subject), and the real. This is an inference that moves towards a conclusion not contained in the premises. At the first level, there is undifferentiation between them; the real is assimilated to the schemata and the only possibilities are some observable variations. At the second level, the assimilatory schemata are multiplied and the procedures come to bear on the objects, producing re-equilibrations and differentiations of new possibilities. Finally, these possibles, in their heterogeneity, give place through intellectual operation abstractions, in a relative way, to “closed” systems and reach the level of logical necessity required. The main problem with this perspective is that it does not analyze the conditions of the sociocultural context in which possibilities are constructed. In other words, cultural mediations must be considered when analyzing the subjects’ constructive activity, along with the fact that such activity occurs in their interactions with others (Martí and Rodríguez 2012).

Vygotsky

According to his principal hypothesis, dialectics in psychological research should play the same role as in Marx’s *Das Kapital* (Vygotsky 1927/1991), serving as model to the genetic study of how to approach a research object’s movements, reconstructing it according to its history and the complexity of its bonds. The main problem for Vygotsky was how to build the units of analysis

requires in order to transfer this method to the field of psychological research: a process of development as a totality would be studied in terms of the unit and the mutual opposition of its own processes. Among others, Vygotsky identified the meaning of words, differentiating between two planes of language, but in their interaction. The inner meaning, or the semantic aspect of language, is associated with social communication processes, with external audible speech. In contrast to what occurs in a fragmented approach, the language unit is not homogeneous but complex, consisting of relations that avoid the isolation of the inner and external components and of the social and individual meaning of the word. The meaning of the word includes relations and contradictions such as the tensions between the external and the inner, individual and society (Vygotsky 1933/1994).

Vygotsky (1927/1991; 1931/1995; 1933/1994) proposed an explanation of the appearance of higher forms of regulation, identified with the mastery of the semiotic means. His main argument is that the human activities system is “open” in the sense that the organic activity is articulated with the use of tools, basically signs. It is important to note the novel features of this system, which combine biological and cultural processes. The two systems are jointly developed, forming a third and unique system of activity which defines the dialectical unit of tensions between the natural and cultural areas of ontogenetic development. This “complex synthesis” is also the result of a genetic and comparative methodological perspective.

In developmental theory, higher psychological functions are developed according to a dialectical process that can be attributed to Hegel, a process “in itself,” “beyond itself,” and “for itself.” Studies of aborted or unsuccessful movements of a baby reaching for an object show that another person later interprets this movement as an indicative gesture and then hands the object to the baby. Ultimately, the baby learns to relate her ineffective movement with the entire situation and comes to consider it an indication for someone else to pass her the object. In other words, the baby becomes herself through others, in a Hegel-inspired

sequence, to provide insight into how subjectivity takes shape and how concepts are formed from the perspective of cultural appropriation in one's relationship with others.

To interpret the meaning of the units of analysis capable of capturing the complexity of such phenomena, Vygotsky's early work on artistic production (1972) also proves insightful. This work reveals that the idea of the functional system in developmental psychology is already present in the idea of the literary system as a dynamic unit of form and content. Later, the functional system considers the effects of this dialectical relation on the aesthetic reaction and also the cathartic processes as described by Aristotle. In other words, the semiotic study of artistic production anticipated that of higher psychological processes.

In Vygotsky's last work, experience – the “live-lihood of meaning” – is an original unit of analysis and also constitutes an affective synthesis of the individual and her cultural surroundings. Experience expresses the characteristics of the body and the context, allowing a certain way of appreciating and signifying reality to be interpreted in a unit of sociocultural and personal aspects. In this interplay of negotiations and resistance, each person appropriates culture in her own way. Furthermore, experience can also be considered in terms of creating and recreating culture, a “novel” synthesis of participative appropriations in symbolic spaces. The author even proposed an empirical model, though it was never finished (Valsiner 2015).

Possibility as Potentiality

The question of the possible can be tentatively addressed in terms of potentiality, provided the formation of potential concepts is considered along with the dialectics of the zone of proximal development (ZPD) (see chapter ► “Zone of Proximal Development”) – the movement of learners in between their potential and actual knowledge.

In general terms, the formation of “scientific” concepts from complexes traverses a level of pseudoconcepts, a form of thinking in complexes that, as such, already contains the nucleus of the genuine concept that is developed within

(Vygotsky 1993/1994). This thinking in complexes can be understood as a preliminary step for conceptual thinking. Whereas the former is bounded by objective connections in-between objects, the latter is abstract and based on logic forms of interrelation. The objective meanings of speech are integrated with the subject's appropriation processes, contradictory elements in a changing functional unit. Conceptual appropriation involves a synthesis of contradictory elements, a sort of fluctuating functional unit during development.

To form such a concept it is also necessary to abstract, to single out elements, and to view the abstracted elements apart from the totality of the concrete experience in which they are embedded. In the formation of a genuine concept, joining is as important as separating: synthesis and analysis are mutually presumed, and during the development of abstraction, the grouping of objects based on maximum similarity is substituted by grouping based on a single attribute (e.g., only round objects). This abstraction destroys the concrete totality of the qualities, thus becoming accessible by joining the characteristics based on different criteria, those of the scientific concept. The potential concepts are precisely the predecessors that make scientific concepts possible. Due to their prevalence even in thinking in complex, the abstraction of a quality is unstable. It does not hold a favorable position and easily cedes its domain to other qualities. Only the domain of abstraction – combined with advanced thinking in complexes – makes it possible to progress towards the formation of true concepts.

Later, the separately abstracted qualities are synthesized anew in an abstract way and the scientific concept emerges, becoming the principal thinking tool. In summary, elementary mental functions participate in a dialectical combination guided by the use of words, synthesizing the qualities and symbolizing them through a sign. Finally, Vygotsky (1933/1994) characterized the zone of proximal development in dynamic terms, describing how children's development and cultural resources are mutually dependent. The ZPD is thus a process of radical change or restructuring of what the individual knows, starting at a stable

moment and then traversing a certain level of chaos and disorganization of the function, like language, play, or concepts. Novelty is a dialectical reorganization of the development process guided by teaching-learning, going from what one knows to what one will know “with someone else’s help.” The new synthesis can be considered a path out of crisis, giving way to new forms of the higher function. ZPD is a theoretical term that covers a set of immediate possibilities, though only one can be actualized in development. With this outcome as a starting point, other possibilities cannot be known (Valsiner 1997). Yet Vygotsky’s work did not adequately address the specification required for the investigation of the transition from potential to realization, or its “operationalization.” This is, perhaps, because the author’s works on maturity did not sufficiently emphasize the dialectical synthesis, the only process capable of revealing the actualization of potential development (Valsiner and Van der Veer 1993).

Valsiner’s Approach

As in the case of Piaget and Vygotsky, the dialectics of development for Valsiner is, primarily, a perspective on how science can be done (Valsiner 2012a, b). Focused on the methodology cycle, the dialectics of development cannot be reduced to research “methods,” particularly quantification. Instead, a process that includes ontological assumptions, methods, phenomena, theory, and data built by the holistic researcher. This methodological cycle treats psychology as a whole, integrating components from empirical phenomena to philosophical assumptions. In this sense, a whole-some knowledge construction cycle recognizes where knowledge is faulty, and this constant recognition leads to new knowledge. Developmental psychology studies the appearance of new totalities based on prior totalities through the resolution of conflicts or contractions that are crucial for the methodology cycle. Clearly inspired by Hegel, the aim is the emergence of superior totalities, based on the inner tension of other systems, positioning qualitative development at the heart of developmental psychology.

Valsiner (2012a, b) acknowledges that different schools within developmental psychology recently adopted a dialectical focus, though the unit of the opposites proposed in these schools have not successfully produced a creative synthesis: one of the opposites dominates, or the opposition is sustained indefinitely and does not allow novelty to emerge. In my view, this limitation does not correspond to Piaget’s description of natural contradictions or dialectical inferences; obviously, it does not fit with Vygotsky’s thinking either, though it is characteristic of Anglo-Saxon interactionism (Valsiner 2012a). Now, the secret to dialectics cannot be found in the harmonious tension between the thesis (A) and its antithesis (non-A), a dialectic with a dual structure so typical of the Anglo-Saxon world (Valsiner 2012a) where finally a choice is made between one of the two. In contrast, it is necessary to sustain a nonharmonious tension between A and non-A, which becomes a necessary condition for a creative but interminable synthesis to overcome the tension. The synthesis occurs when the tension between A and non-A reaches a “breaking point” or “double negation” equivalent to a qualitative jump. Thus, a person experiences tension in relation to one object or another, leading to a reorganization of her affective or aesthetic life, or another generalized feeling. Opposing feelings cancel each other out and the new more generalized feeling appears as an intuition or an opening, though it can also render the appropriation of the generated affect impossible. In summary, synthesis is the most relevant phase of dialectics for this version of development, since it mainly deals with novelty.

On the other hand, Valsiner’s dialectical approach is principally a theoretical outline that lacks adequate operationalization, as was the case for Vygotsky’s ZPD. In any case, certain levels of experience are considered in the construction of dialectics in the theoretical investigation, which is not derived from pure *a priori* abstractions. In this regard, his approach is similar to that of Piaget or Vygotsky. The researcher, however, should seize on the ambivalence that characterizes these processes since they produce the tensions between opposing processes and the ruptures that allow for restructuring.

Potentiality and Actuality

In terms of the distinction between the possible and the actual, a study of psychological development requires examining how an actual event – that may well have not occurred – is constructed through a semi-open-ended set of possibilities in cases where the aim is to capture novelty, something Valsiner has insisted on (along with Piaget and Vygotsky, each from his own perspective). On the contrary, the failure of existing psychology to explain this transition has been evident: psychology has addressed how the actual occurs but without relating this to the possibility of it occurring or to what could but will not necessarily occur. In this regard, cognitive psychology research procedures take the actual as a performance, as a derivation of “competences” or as individual heritage, separated from its contextual conditions. Clearly, as discussed earlier, this argument contradicts Aristotle, using potentiality to make the act evident, as if development were pre-formed.

In contrast, when thinking about dialectical development, the actual is a construction from the possibilities permitted by an earlier level of development, understood as a system of the organism’s interactions with the medium or of an individual’s interactions with the semiotic world in irreversible time (Valsiner 2011). At a relatively late stage of this interaction, a range of possibilities for the elaboration of new functions appears.

Valsiner (2006) sets the prediction of performances as future events – a prediction that corresponds to information processing theory – against the production of novelties, which supposes the unpredictability of developmental paths. Novelties are only produced if development is defined as a constructive transformation of the form or the functions in irreversible time, through processes of exchange and the interpenetration of the organism and the medium. These can be a small expression of a set of possibilities stemming from prior states in the interaction. The author considers that these prior states enable certain paths to transformation, though there is never an infinite set of possibilities. Furthermore, there are cultural signs that act as inhibitors or promoters of

dialectical transformations, which occur under certain conditions. Therefore, it is impossible to predict in detail future performances based on prior ones.

As a result, the complex interactions and interdependence of the organism and the world must be considered in the contexts in which they occur (Valsiner 1997). Likewise, the hypothesis is that the dialectical perspective, by taking on the tensions of opposites, gives way to the synthesis of an “unpredictable” novelty. This contradicts the mainstream belief that psychology is a science dealing with mutually exclusive functions (like child–parent attachment or the lack thereof), instead of the unity of opposites, a science that seeks control and prediction of behavior (Valsiner 2012a).

Conclusions

Dialectics is basically understood here as a perspective that allows different issues of development to be explored, not as the “application” of a philosophical thesis. The range of analyses can be seen in Piaget’s, Vygotsky’s, and Valsiner’s approaches to thinking about the possible and the actual in development. All of these perspectives leave unresolved issues that should be analyzed.

In Piaget, dialectics is presented as a methodology in more classic terms but stands out from Hegelian dialectic in that it examines not only the inferences that stem from contradictions but mainly those that stem from constructive processes. The possible is seen from an epistemological perspective, contradicting innatist or preformationist perspectives in which the possible precedes its cognitive construction. Similarly, the epistemological approach contrasts with empiricist hypotheses of what is already given in the observable world as a construction that can be articulated with the necessary and the real in a process. The dynamic of the possible and the actual is interpreted from the theory of equilibration and associated with dialectical inferences, particularly the process of undifferentiation, differentiation and integration. Its studies, however,

have a serious weakness: they do not include culture or semiotic aspects in the elaboration of the dialectical framework.

In the case of Vygotsky, dialectics as a methodology and its realization in the theory of development follows Marx “stand on its feet” stance over Hegelian propositions (human activity-based dialectics) elaborating a systemic explanation of the novelty of higher functions. With regards to the possible, the transformation of everyday concepts includes simplifying abstractions that constitute, on the one hand, a potential instance for scientific concepts. A student’s real knowledge is, on the other hand, transformed into what she can do with someone else’s help. Therefore, the ZPD is characterized by the transformation of the potential into an act and involves dialectics of the dimensions not fully elaborated in this investigation.

In Valsiner, the tensions between opposites are overcome by the synthesis, which gives way to novelty. This is the core of dialectical thinking and it is entirely different from the reiteration of contradictions or non-resolution in current interactionist thinking. In his hypothesis on the passages from the potential to the act, the question of operationalization – the specification of the conditions under which possibilities become qualitative changes – should be addressed in psychological research on development.

Dialogical Self Theory

Hubert J. M. Hermans

Radboud University of Nijmegen, Nijmegen, The Netherlands

Abstract

Dialogical Self Theory studies the self as a “society of mind.” It is neither a mini-theory nor a grand theory, but rather a “bridging theory.” As such it crosses the divisive boundaries of disciplines and subdisciplines so that new and unexpected linkages between these disciplines are created. This article starts with sketching the historical roots of the theory. The central part outlines its main tenets and core concepts. Finally, examples of research methods and fields of practice, inspired by the theory, are presented.

Keywords

Dialogical self theory · Society of mind · Self-society dualism · I-position · Meta-position

Historical Roots

Dialogical Self Theory (DST) (Hermans 2018; Hermans and Gieser 2012; Hermans and Hermans-Konopka 2010) links up two basic concepts, self and dialogue, that have their roots in different psychological or philosophical

traditions. The self goes back to the American pragmatism of theorists like William James and George H. Mead, while dialogue is a central concept in the European tradition, mainly in the works of Mikhail Bakhtin and Martin Buber.

Usually, self and dialogue are seen as different on the internal-external axis. While the self is considered, at least in Western traditions, as a reflexive concept that refers to processes happening “internally,” that is, within the person, dialogue is conceived of as taking place “externally,” that is, between a person and another person who is located outside. By bringing the two concepts together in the composite notion of “dialogical self,” the external is transported to the internal, and, reversibly, the internal is exteriorized to the external. In this way, the self is no longer reified as an “entity in itself” but as a process that is intrinsically relational. As a consequence, the self has no existence separate from society but is *part* of the society. Stronger, the self becomes a “mini-society” or, to borrow a term from Minsky (1986), a “society of mind.” On the other hand, society is not conceived of as “surrounding” the self and having an impact on it as an external “determinant” but as a society-of-selves. It is composed of individuals and groups in communication that have the potential of co-constructing and innovating society on its way to a largely unknown future. An important consequence of this view is that changes and developments in the self automatically imply changes and developments in society at large, and, vice versa, societal changes are directly modifying the self. Self and society are not mutually exclusive but inclusive, and the dialogical self represents and creates communication bridges between them.

Definition of the Dialogical Self

In a most succinct way, the dialogical self can be conceived of as a dynamic multiplicity of *I*-positions in the society of mind (Hermans and Hermans-Konopka 2010). As these positions can be voiced, they enable individuals to be dialogue with the positions of other individuals and groups and, at the same time, with other positions in the

self. In this view, the I has no existence in itself but emerges from its dialogical relationships with the (social) environment and is bound to particular positions in time and space. From a spatial point of view, the embodied I is involved in processes of *positioning* and *counter-positioning*. When the I positions itself, there is always a counter-position, another person or another part of one's self that, explicitly or implicitly, responds to the original position. From a temporal perspective, the embodied I has the possibility to *position* and *reposition* itself in accordance with changes in situation and time. In these processes of positioning, counter-positioning, and repositioning, the I fluctuates among different and even opposed positions, both within the self and between self and perceived or imagined others. Like in the society at large, these positions are involved in relationships of relative dominance and social power, with the consequence that one position can dominate or even silence another one.

As part of sign-mediated interchanges, positions can be voiced so that dialogical relationships among positions can develop. The voices behave like interacting characters in a story or movie, involved in processes of question and answer, speaking and listening, agreement and disagreement, conflicts and struggles, and negotiations and integrations. Each of them has a story to tell about their own experiences from their specific perspective. As different voices, these characters exchange information, knowledge, and stories about their respective *Me*'s, creating a complex, narratively structured self (for the processes of positioning, repositioning, and counter-positioning and their roots in the works of James and Bakhtin, see Hermans and Gieser 2012, introductory chapter).

What Is an *I*-Position?

An *I*-position is a relational act in space and time. It is a way of *placing* oneself toward others and oneself. The act of *I*-positioning is taking a stance vis-à-vis somebody else and, at the same time, toward oneself in the metaphorical space of the self. It is a way of addressing the other and oneself

via verbal or nonverbal orientations and communications. I can open myself to another person, and, at the same time, I become more close to myself. Or, I'm bashing a disliked person, but, when being alone, I can become skeptic of myself when remembering my inappropriate behavior. An *I*-position reflects a process of positioning toward the positions of other people, who, in turn, position themselves toward me (e.g., I position myself as strong toward an opponent and as tender-hearted toward a loving other). In the act of *I*-positioning, there is always a "here" and a "there," both in the communication with the other and in the communication with myself. Between this here and there, a field of tension is stretched in which one makes, physically or virtually, movements from the one to the other and back.

Active and passive tense. The concept of positioning is not only used in the active but also in the passive tense. I'm not only taking a position toward another person, but I'm also *positioned* by the other. I can be treated by others as friendly, intrusive, supporting, abusing, or abnormal, and such characterizations can be in agreement with or in contrast to the way I position myself. I have the possibility to develop *counter-positions* that are, in the broadest sense of the term, social responses from positions that are *different* from the way others see or treat me. As participating in society, we are positioned as belonging to a particular social category on the basis of our age, sex, gender, skin color, culture, or nationality. On our turn, we may respond to these categorizations with counter-identities (e.g., not agreeing with binary classifications and seeing myself as transgender or as developing a multiple cultural identity in a situation in which others see me as belonging to my culture of origin only). Such processes of positioning and counter-positioning take place not only on the individual but also on the collective level. *I*-positions then have the quality of *we*-positions in the form of collective identities. On their turn, these identities shape our *I*-positions or trigger counter-positions (e.g., as an immigrant I felt not fully accepted in this country, but finally I have struggled to find my own place). In this way, positioning, being positioned by others, and

counter-positioning are expressions of ongoing dialogical processes that take place in the self as part of social, societal, and historical developments.

Meta-position as Helicopter View

In a democratically organized society, many committees, cross-disciplinary teams, or ombudspersons are at work, with the aim to get an overview of the complexity of a particular problem area as a basis for advices or action programs. Typically, such individuals or groups are concerned about taking a long-term view of the problem at hand. In the self as a society of mind, similar processes are taking place. A “meta-position,” like metacognition, provides an overview of more specific *I*-positions, including their patterns and interrelationships. Such a concept is indispensable for a “distance view” on the diversity and complexity of more specific *I*-positions and the ways in which they are organized. What is the nature of a meta-position and which functions does it have?

A meta-position is a helicopter view that has several specific qualities: (a) it takes an optimal *distance* toward other, more specific, positions, although it may be colored by some specific positions more than others (e.g., an ironic position or a sad one); (b) it allows taking an *overarching* view of a multiplicity of positions so that they are seen simultaneously and in their interconnections; (c) it enables to link positions as part of one’s personal *history* and the collective history of one’s group or culture; (d) in linking past, present, and future, a meta-position permits a *long-term* view of the self; and (e) it leads to an *evaluation* of specific positions and the way they are organized; as a result of this evaluation, some positions are prioritized above others, and the degree of automaticity of positions is reduced. In summary, the development of a meta-position with a broad-scope and long-term perspective contributes, more than most other positions, to the cohesion and continuity of the self as a whole (Hermans and Hermans-Konopka 2010).

A meta-position has three functions for the organization of the self: centralizing, executive,

and signaling. As *centralizing* it brings different and even opposed positions together so that their organization and mutual linkages can be considered, preventing the self from becoming fragmented. The centralizing function is particularly relevant in a globalizing and border-crossing society involved in permanent change and at risk of fragmentation. In its *executive* function, a meta-position provides a basis for decision-making and action programs, taking advantage from the insight in the nature of the specific *I*-positions and their organization. As *signaling*, it functions as a stop signal for automatic and habitual behavior enabling the self to become liberated from rigidly established or maladaptive patterns of positions. Evaluating them from a broad-scope and long-term perspective increases the chances for innovation of significant parts of the self.

We are living in a compressed world with highly advanced communication technologies and, at the same time, confronted with apparent differences in points of view on complex problems, like abortion, euthanasia, minority groups, asylum seekers, the rights of transgender people, climate change, genetic manipulation of food, vaccination of children, and the increasing impact of robots and algorithms in our everyday lives. In their communication about such emotionally laden problems, participants are often constrained by short-term perspectives and are at risk of making impulsive decisions. Therefore, the existence and development of meta-positions with a broad-scope and long-term perspective are indispensable as they enable participants to take a big picture view.

Promoter Positions as Openness to the Future

Leaders in teams, organizations, and countries have the important role to empower the members of these social units and to stimulate their future development. Promoter positions in the self as a society of mind have similar functions. A simple thought experiment may clarify why promoter positions are indispensable for the organization of the self. Suppose that each specific position in

the self would follow its own trajectory, not taking into account the direction of the other positions. This would result in a cacophony of *I*-positions, each having their own voice and realizing their own specific goals irrespective of what the other positions tell and what their purposes would be. The existence and development of promoter positions as “leaders” in the organization of the self prevent the self to arrive in a situation of fragmentation and chaos.

Individuals differ considerably in the nature of their promoter positions. For some it may be “my mission in life,” and for others it may be “I as devoted parent,” “I as an innovative scientist,” “I as an ambitious entrepreneur,” “I as a dedicated volunteer,” “I as deeply religious,” or any other constructive power that, as a motivational source, gives direction and continuity to the self in the long run. What these examples have in common is that they represent driving forces in the self that influence the organization of the position repertoire as a whole and have the potential to generate new, more specific *I*-positions (e.g., as a professor I visit other countries, meet new colleagues, have meetings with students, write a book, develop my creativity, etc.). Promoter positions are not fixed for life. Someone can be committed to a long-term goal but later makes a transition toward a new promoter position. Think of a person who made a career as an ambitious professional but later decides to work as a mentor for younger colleagues. Moreover, one person may be devoted to the development of different promoters, involved in organizing different parts of the self.

Promoters in the self have some characteristics that are analogous to promoting leaders in society: (a) they *organize* and give *direction* to a diversity of more specialized *I*-positions that otherwise would go their own way; they have a “compass function” for the self-system as a whole and take care of setting common purposes; (b) they imply a considerable *openness* toward the future and have the potential to *generate new positions* that are relevant to the further development of the self; (c) they *integrate* a diversity of new and already existing positions in the self in the sense that different positions are brought together to form adaptive and productive combinations; (d) they

have the potential to contribute to the *democratic organization* of the self (Hermans 2018), allowing a diversity of specific *I*-positions to have a voice in the organization of the self; and (e) they function as “guards” of the *continuity* of the self, but, at the same time, they create room for *discontinuity*. Whereas continuity is provided by their ability to link the past, present, and future of the self, discontinuity results from the fact that they generate new positions that require a new balance in the self. As generating possible positions, promoter positions function as innovators of the self.

Although promoter and meta-positions may “cooperate” very well with each other, there are several differences. While a meta-position is a *spatial* concept providing an encompassing view on large parts of the self-system, a promoter position has *temporal* aims as it gives an impetus to one’s future development. While a meta-position works as a vertically ascending and descending “helicopter” allowing a self-reflective distance view on the landscape of the self, a promoter position is analogous to a motor pushing the “machinery” of the self forward at a horizontal plane. Whereas a meta-position stimulates reflection on the content and organization of the specific positions, a promoter position gives this organization a push in order to lift it up to a more advanced level of functioning.

Internal and External Positions: Beyond Self-Society Dualism

In agreement with James’s (1890) notion of self-extension, the self in DST is not limited to the boundaries of the skin. Individuals, groups, and even objects that are significant to the self belong to its extended domain (e.g., my parents, my children, my friends, my sports club, my country, my house). In this way DST avoids any self-other or self-society dualism. The other and, more broadly, society are not considered as the environment of the self but as its basic constituents. When society becomes more complex, the self also becomes more complex. When our social environment becomes more heterogeneous, our self becomes increasingly multiple and diverse. And when

society is involved in rapid change, also the self changes at a higher speed. The self is more than a “container” in which the particulars of the self are buried (Callero 2003).

On the basis of these considerations, DST makes a distinction between internal positions and external (extended) positions. However, including a significant other as external positions or as “other-in-the-self” does not mean that the other is an exact copy of the actual other’s perspective. Already Cooley (1902) was aware of this when proposing his “looking glass self” that does not reflect how others actually see us but rather how we *believe* others see us. Inspired by this idea, Shrauger and Schoeneman (1979) reviewed research on the relationship between self-perceptions and evaluations of the self by others. They concluded that people’s self-perceptions are substantially in agreement with the way they perceive themselves as being viewed by others. In addition, they found that there is no consistent agreement between people’s self-perceptions and how they are actually viewed by others. This finding suggests that an external *I*-position or the other-in-the-self is a subjective construction that is not necessarily in agreement with the actual voices of the others. DST assumes that external *I*-positions are, at least for a great deal, constructions in the service of the needs, aspirations, and imaginations of internal *I*-positions. However, when external *I*-positions would become purely subjective constructions, they would become ultimately illusory or even delusory. Therefore, DST assumes that the self, including its external *I*-positions, requires contact with the actual other in order to correct itself and to maintain a minimally realistic image of the other as part of the extended self.

The inclusion of significant others and groups as external positions of the self has implications for the conception of others as meta- and promoter positions. A meta-position is not a purely internal process. Rather, it is co-constructed by others. Self-reflection from a meta-point of view can take place (and may be different) in a dialogical contact with a friend or in reading an impressive book or listening to deeply inspiring music. Significant others may also function as external

promoter positions in the self. For some it may be an iconic person who reaches the status of a hero or heroine, like a Mandela, a Ghandi, a Malala Yousafsai, a pop artist, or an imaginary figure from a book or film. For others it may be a person living in one’s immediate environment: a parent, a grandparent, a dedicated friend, or a coach. Such people are adopted in the virtual space of the extended domain of the self and become established as valuable sources of energy. [For other central concepts of DST, see Hermans and Hermans-Konopka 2010].

Methods and Fields of Practice

In the course of time, DST has led to the construction of different methods and to applications in different fields of practice. Some of them will be described here.

Self-Confrontation Method. This method (Hermans and Hermans-Jansen 1995) is an idiographic procedure that invites clients, in cooperation with a coach, to formulate narrative meaning units about their past, present, and future in the form of a series of short sentences. Each sentence is then connected with a series of affect terms referring to positive affect (e.g., joy and enjoyment) and negative affect (e.g., anxiety and powerlessness). Moreover, a distinction is made between affect referring to self-assertion (e.g., pride and self-esteem) and affect referring to connection (e.g., love and tenderness). The purpose is to create an organized system of sentences and affect terms that help the client to formulate plans for future actions. This dialogical method is constructed not as a usual psychological test or questionnaire but as a cooperation between psychologist and client with clients as co-investigators of their own situation.

Personal Position Repertoire (PPR) Method. This method (Hermans 2001) assesses a client’s main internal positions and external positions and connects them in a matrix. The entries of the matrix refer to the extent to which a particular internal position comes to the fore in relation to a particular external position. Sum scores are calculated that show which internal positions and

which external positions are most prominent or least prominent in the repertoire as a whole. Via the calculation of correlations between internal positions and between external positions, the method allows to discover connections that are typically below the client's level of awareness. The purpose of this method is to create insight in the content and organization of the position repertoire.

Composition Work. This method (Konopka and van Beers 2014) is inspired not only by DST but also by the philosophy of Japanese gardens. The basic material is a pool of stones that differ in color, form, size, and texture. Clients select those stones that they feel as significant to their own experience. Each stone represents a particular internal or external *I*-position. The stones are then placed in such a way that a composition emerges that reflects the organization of the repertoire. Some positions are more central, other ones more peripheral. Some are dominant, and other ones are neglected or suppressed. Typically, stones are placed in subgroups so that positions that stimulate the clients' development and those that impede it become visible. This method is sensorial and embodied and can be used to study the less conscious layers of the position system.

Fields of Practice. There are four main fields in which DST has been applied. Studies of the dialogical self in *education* are brought together by Meijers and Hermans (2018) with attention to the stimulation of dialogue and dialogical self in the classroom. Applications of DST in *psychotherapy* are collected by Konopka et al. (2019) with contributions from different therapeutic schools and different cultures. Applications in *work and organization* are put together by Hermans (2016) with a focus on forms of assessment and stimulation of a dialogical self. Finally, studies in which DST is applied in the field of *culture* are regularly published in the journal *Culture and Psychology* since 2001 (Valsiner 2019).

In summary, DST conceives of the self as a society of mind that is organized on the basis of dialogical relationships with attention to relationships of dominance and social power. As a bridging theory, it links different theories and conceptual

traditions, has produced a variety of methods, and is applied in different fields of practice. Its dialogical structure provides a basis for the study of the possibilities of the human mind.

Dialogism

Fiona Maine and Rupert Wegerif
University of Cambridge, Cambridge, UK

Abstract

The first recorded use of the term dialogic refers to novels in the form of a dialogue. The philosopher Mikhail Bakhtin extended this meaning to refer to novels, such as those of Dostoevsky, where multiple characters interact with different points of view which are not reduced to a single reality. For Bakhtin and the Bakhtin circle, dialogism was extended beyond literature to become a general theory of meaning. Meaning is not contained by words and utterances but is found only in the dialogue between them and their context. The meaning of what is said in a dialogue is a response to things that have been said before and an anticipation of things that will be said in response. One implication of this is that wherever there is meaning there is more than one voice in play. Another implication is that there are no final meanings, only an ongoing open dialogue. Dialogic is a contrast to monologic or the view that there is a single correct voice or correct and final view of things. Dialogism has been applied to studies of literature and to the theory of education. Dialogic education has been described as opening a “dialogic space” which is a space of possibilities, widening and expanding that space. In this entry we focus, in particular, on dialogism in education where it is applied as a way to promote a particular kind of possibility thinking.

Keywords

Dialogue · Dialogic · Education · Possibility thinking

Introduction

“Dialogism” is the theory that meaning is “dialogic” where dialogic means “like a dialogue.”

Crucially, according to widely referenced dictionaries such as Merriam-Webster and the Oxford English Dictionary, it suggests the presence of more than one voice. Dialogue comes from a combination of the Greek for “across” – dia and Greek for “speech” – logos, so the implication is that through talking together, meanings are made. But the Greek word “logos” is resonant with many meanings including that of “reason” or “thought” so the terms “dialogue” and “dialogic” are not necessarily limited to language. In cultural studies, for example, the notion of “intercultural dialogue” refers to a much broader concept of sharing and understanding cultural identities, heritages, and practices. The Council of Europe (2008 pp. 10-11) defines intercultural dialogue in its White Paper on Intercultural Dialogue as follows:

Intercultural dialogue is understood as an open and respectful exchange of views between individuals, groups with different ethnic, cultural, religious and linguistic backgrounds and heritage on the basis of mutual understanding and respect [--]. It operates at all levels – within societies, between the societies of Europe and between Europe and the wider world.

Additionally, writers (see, for example, Maine 2015) have described dialogue as an interaction between readers and “texts” such as books, films, or even computer games. Other artistic and creative practices that include a collaboration of more than one voice – jazz, modern dance, and improvisational theatre – can all be viewed as dialogic interactions.

This entry explores the deeper implications of the use of “dialogism” as a term, drawing on its historical traditions and influences, but with a mind to the “possible” and the relationship between dialogism and possibility, situated by a concept of dialogism as opening up a plurality of perspectives, indeed, a potentially infinite or unbounded number of perspectives (Wegerif 2013). Dialogism – the idea of many voices – sits in opposition to monologism, the single truth and authoritative voice claimed by positivism. In other words, in dialogue meanings are made and remade infinitely, as for each “response” multiple new possibilities exist as new meanings are negotiated, either in the practice of small “d” dialogism – talk itself or within the larger big “D” dialogue of (socio-) cultural context

(following Gee's 2015 similar discussion about Discourses). Truths are not singular and non-contestable (monologic) but open to interpretation, challenge, reconceptualization, and transformation. The generation of knowledge from a dialogic perspective assumes collaboration and plurality. It also assumes questioning, and thus, answering. Bakhtin, a philosopher regularly associated with the concept of dialogue in education and literary studies, argues that, "If an answer does not give rise to a new question from itself, it falls out of the dialogue" (Bakhtin 1986 p. 168). For Bakhtin the inter-animation of different perspectives can lead to mutual illumination. Hence for new knowledge and meaning, more than one voice means more than one perspective, an inherent tension between ideas that leads to either resolution or acceptance of plurality. Technically from a dialogic perspective, individual utterances are meaningless until they are considered in their context. Linell (2001) argues that the difference between monologism and dialogism is precisely that, as, "whilst monologism assumes individuals and societies (cultures) to be analytical primes, dialogism takes *actions and interactions*, e.g. the discursive practices, *in their contexts* as basic units" (p. 7). In other words, it is the placement of utterances within the context of what has come before (the question), and then what can possibly come in response (the answer, and then further questions) that builds new knowledge. Engagement in dialogue then transforms us and our reality as we continually reinterpret it and our sense of ourselves. It is the posing of questions and seeking the possibilities of "what might be" that makes dialogism a relevant entry in an Encyclopedia of the Possible.

History of Dialogism

Although the first use of the term "dialogic" was for novels in the form of dialogues between two or more characters, the theory of dialogism has deeper roots. The origins of dialogism can be traced to oral educational practices that came before the focus on print literacy. Buddhist traditions, Confucian education, traditional Jewish education, and the Islamic small group "*Halaqat al-'Ilm*" or circles of knowledge (Makdissi 1990

p. 210) all have dialogic associations. A direct thread through the history of dialogism in the Western tradition ties back to the teachings, and dialogic approach to pedagogy, of Socrates. For Socrates, the growing use of alphabetic writing in education was cause for concern as he felt that it was the face-to-face dialogic interaction where true intelligence could be found (as reported in the *Phaedrus*, a dialogue with Socrates written by Plato). This concern echoes the argument about monologism and dialogism; for Socrates, the fixity of writing meant meanings could not be challenged and developed, only "in the moment" could ideas be expanded.

Buber

Buber, a philosopher of the mid-twentieth century centralizes dialogism through his writing on the difference between Ich-Es (I-It) and Ich-Du (I-Thou) as ontological stances. As essentially monologic, he describes the I-It stance as objective and removed, separating the subject from the object, with "I" rooted in the past, presenting a single, fixed perspective. Alternatively, an I-thou stance is an inherently relational, reciprocal, and dialogic positioning of oneself in relation to another. Dialogue is an experience of wholeness and the relationship between I and Thou is mutual, "[M]y *Thou* affects me, as I affect it" (Buber 1958 p.12).

In earlier work, Buber (1947) used the term "genuine dialogue" to describe "where each of the participants really has in mind the other or others in their present and particular being and turns to them with the intention of establishing a living mutual relation between himself and them" (1947 p. 22). However, Buber warned against the loss of one's own perspective in empathizing with another viewpoint; being able to balance differing perspectives in tension with each other and tolerating the ambiguity of not having concrete conclusions adds to the sense of dialogue as having an ongoing, forward-looking momentum.

Bakhtin

Bakhtin is the modern philosopher and literary theorist most commonly associated with theories about dialogism. He was particularly influenced by both Socrates and Buber in his writing about

the distinction between the “authoritative word” (monologic, fixed, and objective) and the “persuasive word” (dialogic and fluid). For Bakhtin,

The internally persuasive word is half-ours and half-someone else’s. Its creativity and productiveness consist precisely in the fact that such a word awakens new and independent words, that it organizes masses of our words from within, and does not remain in an isolated and static condition. (Bakhtin 1981 p. 343)

Bakhtin is also associated with the idea that dialogue is never-ending or infinite – as response is always possible, and in fact, implied.

Dialogism and Education Theory

If, essentially, dialogism is based on questioning and inquiry, an engagement and relationship with the world, then it is not surprising that notions of dialogism have gained much purchase in educational theories in the last century. Dewey’s argument that all children should be taught to make sense of the world, “with ardent curiosity, fertile imagination and love of experimental inquiry” (Dewey 1933 p. v) is profoundly dialogic, as with each new inquiry comes response and further inquiry. Another influence on modern approaches to dialogic education writing at the same time as Dewey, Mead (1934) suggested that the development of reasoning is dependent on engagement with a “generalized other” and on situating a line of argument into the wider context of being accountable to a community of reasonable people. This situating of argument within the context of multiple perspectives brings to the fore the dialogism enacted by engaging with others.

Dialogism can also be traced in the work of another key educational theorist of the twentieth century, Vygotsky. His work, focused on the transaction of meaning making between More Knowledgeable Others and learners, highlights language as a tool for learning (1986), and hence sits behind many dialogic teaching approaches (Alexander 2020). Vygotsky describes the internalizing of dialogue into inner thought, linking to Bakhtin’s notion of dialogue with culturally embodied voices. More recently the work of Neil Mercer

and colleagues has centralized the importance of “interthinking” as the collaborative touchstone of meaning-making (Mercer and Littleton 2007).

Taking a more political stance, the work of Freire centralizes the role of dialogue in the empowerment of “the oppressed” (2000). He argues, “without dialogue there is no communication and without communication there can be no true education” (2000 p. 92). Dialogue enables us to “name” the world and he claims, “this dialogue cannot be reduced to the act of one person’s ‘depositing’ ideas in another, nor can it become a simple exchange of ideas to be ‘consumed’ by the discussants” (ibid. p. 89). Freire reasons that there are three core aspects to dialogic education: first, the importance of starting with the lived experience of students; second, the idea that dialogic education is about making a real difference in the world through empowerment or giving a voice to those initially without a voice; and finally, the importance of genuine respect and collaboration between educator and student so that meaning can be co-constructed rather than imposed.

Dialogic Teaching Approaches

The name most commonly associated with dialogic teaching in the UK is Robin Alexander (2020). Following a study in five different countries investigating the role of talk in the classroom, he identified five (and more recently added a sixth) principles that he said epitomized a dialogic approach to teaching. Alexander acknowledges that his principles fall into two categories. Firstly, there are those depicting a classroom ethos; these include values around creating a collective endeavor, a supportive environment where students are comfortable in expressing their view, and a reciprocal environment where students listen to each other. The second set of principles relate to the talk itself. Alexander argues that talk should be purposeful with clear learning intent, that it should be cumulative, with ideas working together, and that it should be deliberative, with participants striving to resolve different points of view (2020 p. 131). This final principal potentially sets Alexander’s framework at odds with concept of dialogue promoted by Bakhtin and captured by

Wegerif's (2013) description of "infinitezability." If dialogue celebrates plurality and multiple viewpoints, then the end point is not always to seek agreement, but potentially to tolerate the ambiguity and uncertainty that there are not always resolvable differences of opinion. Other educationalists championing "educational dialogue" also place emphasis on the importance of seeking resolution (see for example Howe et al. 2019). Yet this mode of argumentation, while arguably promoting cognitive growth, does not fully reflect the more Bakhtinian, or Buberian heart of dialogue, even if it does echo the persistence of questioning and reasoning in the teachings of Socrates. In further criticism of dialogic approaches that also have clear learning goals, Matusov (in Matusov and Wegerif 2014) argues that because dialogues are open-ended, a clear purpose and learning outcome is essentially non-dialogic. In response to this assertion, Miyasaki (in Matusov and Miyazaki 2014) makes the point that if we have a dialogic relation with the world around us, then subject specialisms such as Science are part of our growth of understanding about the world.

Other programs in schools allow for a more divergent enterprise. The Philosophy for Children (P4C) program, originating in the USA (Lipman 2003) holds at its core a framework of three "C"s of thinking: Creative Thinking, Caring Thinking, and Critical Thinking. With an additional fourth mode, Collaborative Thinking, added for P4C in the UK, this framework allows for celebration of differences. A recent European-wide project, DIALLS (www.dialls2020.eu) similarly placed values of tolerance, empathy, and inclusion at the core of its work teaching children the skills of dialogue. Influenced by the work of Buber, P4C, and Alexander, the project reconceptualized cultural literacy as an innately dialogic social practice (Maine et al. 2019) focusing not only on the development of skills around talk but also an awareness of one's own identity, heritages, and cultural values in relation to those of others.

Dialogic Space

Apparent in the work of Bakhtin and Buber, the notion of a space between voices or perspectives

is, in itself, important. Wegerif (2013) describes in detail the idea of a dialogic space as the place of tension between perspectives. He also argues that there is "an inclusive space of dialogue within which self and other mutually construct and reconstruct each other" (2008 p. 353). This notion of space between is particularly pertinent to this entry as part of an Encyclopedia of the Possible, as it offers just that. Maine (2015) draws on this idea, and the infinite potential of response highlighted by Bakhtin by describing this space as a "Dialogic Space of Possibility" (2015 p. 19). Ideas that exist in this space are inter-subjective, fluid, and provisional. The tension between perspectives is one of possibility of what could be.

However, the potential of this space depends on the speakers whose ideas are shared. Those engaged in possibility thinking (Craft 2000) would inhabit the space with curiosity and imagination, inquiring about "what if..." or "what might be..." Their ideas would build together, at each point both refining and expanding. This space of possibility can be widened and deepened through embracing many perspectives while exploring different views in depth. The language of dialogue itself can support the opening of these fluid and provisional spaces. Hypotheticality and "possibility markers" (Maine 2015 p. 60) such as "might," "maybe," and "perhaps" enable not just speculation and possibility thinking but also a social cohesion leading to collaboration and inter-subjectivity. Boyd and Kong (2017) noted a further value of the use of possibility language in dialogue, that of "reduced commitment" (Boyd and Kong 2017 p. 27) to an idea should it turn out to be non-acceptable to others. This caveat to putting forward an idea enables a tentative or cautious movement of testing the water to see which ideas float in the dialogic space of possibility.

Dialogic Space and Possibility Thinking

Dialogues have to be lived on the inside, they cannot be defined only in terms of the external surface of things: they cannot be reduced to visible countable things as if they were just so many words or bits of data. Wherever dialogue occurs, it

opens up a space of multiplicity and uncertainty – a dialogic space which consists of divergences and resonances between utterances and voices. The opening of this space is the precondition for the possibility of learning something new.

Before a dialogic space opens, things tend to be thought of as located in space using a default identity way of thinking about reality which assumes that “a thing” is what it is and not another “thing.” The pepper and salt pots on the café table are just pepper and salt pots, for example. But when dialogic space opens up, then material things, bodies, hands, voices, gestures, pixels on the screen, become signs for other things and representative of voices that are not present. Depending on the dialogue, the pepper pot could become Lionel Messi scoring a goal for Barcelona dribbling brilliantly around the salt pot and into a goal marked out by knives and forks, or the two pots could represent the relationship between a proton and a neutron in an atom (deuterium in this case) surrounded by an electron cloud of scattered pepper on the table or they could stand in for almost anything at all.

Each opening of dialogic space is unique, but all dialogic spaces, once opened, share something in common. While in practice any given dialogic space might have a limited range of themes and probable outcomes these cannot be determined in advance because, in principle, any real dialogue opens up an infinite potential for creating new meaning. This is just another way of saying that the context that could be brought into play in any dialogue is not bounded, at least not as far as we know. In practice, a group of children in a dialogue might just bring in references from the TV shows that they saw the night before, but in principle anything could be brought to bear on the problem at hand. But, of course, dialogic spaces are also all different in their physical location. Dialogues always open somewhere that could be given a location in space and time and also in terms of cultural and historical context.

Despite the infinite potential for meaning behind every dialogue, in practice dialogic spaces have limits. It is possible to feel when they open and when they close and the range of references

and resonances, the field of perspectives bound into the dialogue, can be more or less wide and more or less deep. Dialogic education includes the moves of *widening* dialogic spaces by bringing in new and different perspectives, talking to different voices about any given topic on the Internet perhaps, and the move of *deepening* dialogic spaces through a process of “de-construction” that unpicks the key distinctions that frame the dialogue problematizing them or putting them into question in order to expand the range of possible thoughts (Wegerif 2013).

Summary

Dialogism has a deep history going back to the oral education practices of Socrates in ancient Greece and in the tradition of every culture. It claims to be the truth that meaning always involves the play of different voices. It is a contrast to the popular notion of monologism, the illusion that there is always one true voice or one true way of seeing, a correct and final representation of things. Recent accounts of dialogism that have influenced education practice have come from Buber, Freire, and Bakhtin. These all speak in different ways of the importance of opening dialogic spaces in education. Dialogic spaces are spaces in which the divergences and resonances between voices allow new possibilities to emerge. The contemporary practice of dialogic education which involves opening dialogic spaces and then expanding them, widening them with new perspectives, and deepening them by questioning any framing assumptions is a specific way of teaching for an increase in awareness of new possibilities.

Dieting · Possible · Health · Weight loss · Disordered eating

Definition

Dieting refers to a common practice with a history of different meanings and associated consequences. Its complexity and controversies have spurred significant scientific attention. When studied empirically, this phenomenon can be investigated using different measurements that generally refer to the history of dieting, a current dieting engagement, or a more specific construct, such as dietary restraint. Its consequences have been widely discussed, with authors highlighting weight loss as a possible end and, on the other hand, adverse consequences, such as weight gain/regain and eating disorder risks. Sociocultural theories, for example, see it as a typical behavior in search of ideal, frequently unattainable health and body. This text mainly focuses on the different senses and meanings of the term and its possible outcomes. To this end, it begins by defining dieting and its history before moving on to summarizing research in the field. Some reflections on how to achieve dieting into the possible are offered toward the end.

The notion of dieting appears in everyday use both by lay discussions and in scientific studies. On the one hand, laypeople mostly understand it as behavior oriented to health or appearance.

Scientific research in this area, on the other hand, brings about concepts ranging from food restriction/control for the prevention/treatment of diseases to dieting as a risk for developing conditions (such as eating disorders), thus overly contributing to understanding the positive and negative implications associated with the term. However, the construct's definitions are still the target of criticism and reflection. In this sense, research on dieting is of interest in many disciplines and has attracted attention from different fields such as medicine, nutrition, psychology, sociology, and anthropology.

Thus, dieting denotes a common type of behavior but can be defined as a multidimensional construct: dieting history, current engagement in dieting, and weight suppression (Lowe 1993). Furthermore, following a diet can have different purposes, which can be gender-mediated, for example. It is a term used to designate conduct taken for clinical treatment or not. As proposed by Lowe and Timko (2004, p. S19): “*depending on what one means by them, dieting can be quite harmful, merely ineffective or actually beneficial.*” Dieting is, therefore, a behavior subject to different meanings. Accordingly, considering that the possible reside in the meeting of perspectives (Glăveanu 2021), it is plausible to suggest that the possible of dieting (as will be argued here) may be subject to mediations related to the different meanings attached to it.

This section will walk us through the history of the definition of dieting. Subsequently, it will continue with a brief review of quantitative and qualitative empirical research on dieting and focus on the sociocultural approach to the term. Finally, a reflection between the concept of dieting and the possible will be proposed.

Definition and History

Dieting is the verb form of the word *diet*. Etymologically, the term *diet* is derived from Greek modifications of the word *diaita*, which described “a way of life” or “regime” (Waife 1955). The concept of *dieting* in popular culture has evolved over time and has been limited to food restriction

aimed at weight control. Such ideas resonate with the general definition listed in the Oxford English Dictionary: “self-restricting to small amounts or special types of foods to lose weight” (Stevenson 2010, p. 8890).

In scientific approaches, the general notion of dieting is also subject to similar meanings, but with distinctions worth highlighting. According to the Dictionary of Medical Terms (Collin 2005, p. 109), when dieting is used as a verbal form, it refers to reducing the amount of food intake or changing the type of food one eats to lose weight or become healthier. While its use as a noun means “the act of trying to reduce weight by decreasing the amount of food intake.” The American Psychological Association argues that dieting can be seen by some health professionals as a solution to obesity and, by others, as a primary pathology associated with eating disorders, like anorexia and bulimia nervosa (APA 2020).

The ambiguity of meanings is also seen in the use of the word *diet*, which can vary depending on the context or region in which it is used. For example, in Nutrition Science, the term *diet* refers explicitly to the prescription of food and drink, in which the quantity and type of food and schedules are regulated for therapeutic purposes (Valentini et al. 2014). Still, depending on the region, the word can also take on different meanings. The French word *diète* is restricted to the diet of patients, while *diet* has a broader approach to the meaning in the English language (Jouanna 2016, p. 211). This ambivalence of meaning opens up what is the possible of human behavior associated with dieting. We can conceptualize it as a behavior related to control, restriction, treatment, and a regular practice associated to a way of life. These differences have been apparent throughout history and suggest that what can be achieved through *diet* or *dieting* may refer to meaning-making dynamics of the possible (Glăveanu 2021).

As mentioned, the current variation of senses and meanings of dieting has been noticed since ancient times. In the classical period, the term *diaita* could refer to the dietary practices of individuals or societies at the time, as attested in the literature and reports by historians (such as

Herodotus), and could also designate the diet of healthy or sick people, judging by the collection of medical works associated with Hippocrates (*Hippocratic Corpus*) (Jouanna 2016, pp. 209–214). Thus, the word *diaita* in the classical Greek context, represented a whole way of life, a complete path to health, and was not restricted to its meaning exclusively related to weight loss, which was intended for corpulent people, whose excess fat was an indicator of ill health and moral conduct related to luxury and depravity (Foxcroft 2011, pp. 20–25). The intertwined relationship between body control and morals could be seen as another angle to explore the possible of dietary practice as an ancient idea.

In the Middle Ages and early Modern era, books on food and meals were still based on classicism's ideas (diet linked to duty and morality). However, such conceptions became more accessible to the general public through the creation of the press. As a result, the Renaissance was marked by the greater reach of the belief that a good diet would lead to better health and a more prosperous society (Foxcroft 2011, pp. 31–34). Nevertheless, in the mid-nineteenth century, dieting takes on the cultural meaning of food restriction for weight loss as we have it today. According to Vester (2010), dieting to lose weight was first a practice aimed at the male audience, which began in Europe, and then spread over to the American continent. It emerged for men as a renegotiation of masculinity and an alert to the dangers of obesity in a culture with a sedentary lifestyle. Later, the logic of self-discipline is adopted by the female gender, with the influence of women's rights activists (see also ► “Feminisms”) who motivated the practice of dieting to encourage women to control their bodies and resist the hegemonic ideals of femininity of the Victorian period. In the 1920s, dieting was consolidated as a widely popular practice spurred on by the meaning of an unpatriotic attitude attributed to waste, indulgence, and overweight (Vester 2010).

In this sense, it is valid to consider the role of normative standards in searching for practices to modify the body, such as dieting. While corpulence represented a trait of desired femininity until

the nineteenth and early twentieth century, in the following decades, figures representing ideas of feminine beauty became increasingly thin (e.g., fashion icon Twiggy in the 1960s), with the growing influence of the advertising industry and the media displaying them (Bonafini and Pozzilli 2010). These changes and contradictions on aesthetic ideals (see also ► “Aesthetics”) help shape the possibility of dieting when we assume that the relationship with food has been consolidated as a way to sculpt the appearance. Another important milestone is the advent of a scientific approach, especially in the early nineteenth century, around the practice of diets, which significantly contributed to foster the meaning of dieting as it is understood today, since scientists and laypeople began to consider the human body as a machine and, later, as a collection of chemical processes (Gilman et al. 2008).

This brief historical report points out that, although under the aegis of different meanings, the diet always has been between an artifact of cultural expression and medical prescription, which evolved under moral values and were later shaped by the attributes of scientific knowledge. Such considerations provide a deeper understanding of *dieting* and how this term can relate to the possible.

Research on Dieting

As mentioned earlier, dieting could mean modifying intake for weight loss or a lifestyle attribute. Since the term is primarily used in the literature to refer to weight loss practice, this will be our focus in this session. An increasing number of studies on dieting have been observed in the last 40 years, which may be related to the phenomenon of obesity and from the understanding that dieting per se can be harmful to health.

Thus, research on dieting can be dichotomized into two fields, one that seeks to understand measures to improve adherence to weight loss recommendations and another that believes that dieting itself is a behavior related to harmful effects on health, and by this must be eliminated (see Putterman and Linden 2004 for a discussion

of this issue). Within these perspectives, the construct can be assessed through scales, questionnaires, or single questions. However, one of the challenges in dieting research is precisely identifying a valid measure of the construct. As previously pointed out by French et al. (1994), generally, single questions are used to assess current engagement in a weight loss diet, while scales identify dieters through behavioral and psychological characteristics. Therefore, when considering the different fields of interest and measures used, research on dieting has many studies, mainly quantitative (observational, psychometric, and experimental), with divergent results.

That said, the belief that energy expenditure would be sufficient to induce weight loss was present in much of the food and nutrition research, based on the premise about the capacity of caloric restriction to induce a negative energy balance. However, the last decades have been marked by new investigations in this field, mainly with the growing obesity. In this vein, Herman and Mack (1975) proposed the Restraint Theory, which supported many of the studies on the negative consequences of dieting on eating behavior and weight. The study of this proposal was conceived by a valid measurement framework, the Restraint Scale (RS) (Herman and Polivy 1980), a one-dimensional ten-item self-reporting instrument designed to identify the restrained eating (or dietary restraint) construct, used interchangeably with dieting. The RS consists of two subscales, one for capturing dieting and the other for weight fluctuation.

Using the RS scale, Polivy and Herman and other researchers showed that chronic dieting correlated with episodes of overeating under stressful conditions, forced preloads or exposure to tempting food stimuli (see Herman and Polivy 2011 for review). However, this scale has been subject to criticism over the years, mainly for inserting overeating within the construct of food restriction, which has led other authors to develop tools to assess food restriction in isolation, such as the Three-Factor Eating Questionnaire (Stunkard and Messick 1985) and the Dutch Eating Behavior Questionnaire (van

Strien et al. 1986). Overall, it is inferred that RS identifies chronic, unsuccessful dieters and TFEQ and DEBQ the successful ones. The use of the restrained eating concept, measured by the above scales, is also questioned to identify the dieting construct. Lowe (1993) reformulated the Restraint Theory proposal through the Three-Factor Model of Dieting and state that dieting can take on three dimensions, assessed by the Dieting and Weight History Questionnaire (DWHQ) (Witt et al. 2013). These theories have different definitions, understandings, and meanings of what dieting is and its implications (see Chen et al. 2021 for review).

Furthermore, population-based studies, using mainly single questions, with samples of adolescent and adult individuals of both genders, showed outcomes such as weight regain and risk of eating disorders. For example, Neumark-Sztainer et al. (2007, 2012) showed that dieting is prevalent and a predictor of weight gain and disordered eating behaviors (such as binge eating, skipping meals, and using diet pills). Other authors have reproduced these findings in different countries and by experimental research, and many are based on the Restraint Theory (Herman and Polivy 1980, 1984). However, dieting's beneficial effects were also observed by other authors in observational and experimental studies. In a review, Lowe and Timko (2004) pointed out some of these results and described studies in which dieting reduced overeating or bulimic symptoms in clinical and non-clinical samples.

Despite the vast amount of observational and intervention studies, qualitative research on experiences and meanings associated with dieting is less robust. Wertheim et al. (1997) reported one of the first investigations of this type, using semi-structured interviews with 30 adolescents from public schools in Victoria, Australia, to assess descriptions and reasons for weight loss attempts. They found that one of the reasons for dieting often involved feeling fat and highlighted media and fashion pressure on teenage girls to be thin. In more recent studies, feeling fat (or improving appearance) also appears as a motivator for dieting in women with eating disorders (Cooper

et al. 2007) or overweight/obesity (Leske et al. 2012), and “being healthier,” which, per findings by de Souza and Ciclitira (2005), is a prominent reason in men.

Regarding the meaning of the term, dieting appears as something “that everyone does” (according to English teenagers, Sharpe et al. 2013) and that can be done in different ways (according to Malaysian women, Ismail et al. 2018) such as “skipping meals” or “removing rice from daily meals.” These accounts are essential to examine the different meanings of the gender-mediated construct, for example, and reflect its relationship with the possible, as we will see below.

Dieting and the Possible

Dieting is connected mainly to changes in weight and eating behavior. While weight loss is explained by the induction of negative energy balance promoted by the diet’s caloric restriction, the unwanted consequences are justified by psychological or biological “diet-defensive” reactions, such as dieting leading to overeating (Herman and Polivy 1984) or reduced metabolic rate/lean mass loss facilitating post-dieting weight regain (Prentice et al. 1991). One of the limitations of overlapping only one viewpoint is the risk of generalizing that dieting is miraculously the means to achieve ideal weight/body loss or is fatally harmful, regardless of who is doing it or how and what it is referring to. Finally, how does one define in which terms the construct fits in?

Lowe (1993, 2015) believe that obtaining this answer requires understanding the type of dieting behavior being referred to. The Three-Factor Diet Model proposed three types of dieting behavior: history of dieting, current dieting to lose weight, and weight suppression (or the difference between individuals’ current weight and their highest previous weight). Thus, rather than claiming that dieting almost invariably leads to negative consequences, they assume that the construct’s facets may be related to its different effects on eating and

weight (harmful or not). They conclude as follows (Chen et al. 2021, p. 28):

Stated differently, asking whether dieting is “good or bad” is analogous to asking if taking methadone is good or bad. If someone goes on a weight loss diet because of preexisting weight gain or loss of control eating, then dieting may improve these conditions, just as taking methadone in place of heroin will reduce risk for harmful outcomes. With 40 years of hindsight, most dieting now appears to be a consequence of our obesogenic environment. Making widespread changes to that environment may be single best way to curb the need for dieting.

Therefore, how does one interpret its senses, meanings, and implications for society? A sociocultural perspective of dieting sees it as a typical behavior (mainly, but not exclusively, of women) motivated by the search for cultural health and body ideals promoted by art, media, and science. Thus, dieting appears as a mean to control bodies, whether from a feminist perspective or a historical analysis of science (medicine), and while at the same time a consequence, it perpetuates the rejection of fat in a contemporary westernized world. Sociocultural theories also postulate the role of Western media in promoting unattainable ideals and leading individuals to internalize them and adopt them as their own, which places measures such as dieting (most often with extreme behaviors) as everyday conduct in an attempt to achieve them. Yet, a system of values around dieting and body can also be understood through the concept of diet culture. This term refers to the social and cultural atmosphere that normalizes weight control (placing dieting as a cultural practice) and fat-phobic bigotry (Tovar 2018, p. 12). According to Davidson (2020), three major aspects compose diet culture, namely, thinness as a way of gaining social power, placing moral value on specific foods and body types, and rigidly associating thin bodies with health. Thus, dieting appears as a means to achieve these values. Putting all into perspective, we can suppose the diet culture transforms a polysemic instrument (i.e., dieting construct) into a normative control device, which adds a symbolic value associated with different consequences, such as the

incessant and fallible search for an unreachable body or attribute.

We can reflect that the possible of dieting addressed in this work can fit in perspectives of results and intersubjective experience. Thus, to outline it, we will start from the understanding of Glăveanu (2021), for whom the possible can be understood as residing in the meeting of perspectives. From a socio-historical conception, we can infer that dieting took on a character of what Vygotsky called “fossilized behavior,” that is, its meaning as we currently understand it faded over time through a long stage of historical development. This process results in a crystallized understanding of the term dieting, in the contemporary world, as a (control) behavior to reach an almost always unattainable ideal. Lowe and collaborators contribute to the reflection on the term’s possible – or the rupture of fossilized behavior – by pointing out that dieting can be mediated by the different perspectives it takes. In this sense, if we consider that dieting takes on other dimensions, the concept can recover different meanings, such as care. However, for this possibility to be forthcoming, it is necessary to reflect on something at the root of the perpetuation of the restricted meaning of the term: the diet culture. Thus, to expand the possibilities linked to dieting and give new meaning to it, it is essential to overcome the tension established in a society that interprets dieting as an instrument to achieve a perfect idealized body for obtaining intangible happiness.

Conclusion

Dieting is a common experience that plays a vital role in subjects’ lives and displays different senses, meanings, and results depending on the mediations when exploring the possible, including the individual’s viewpoint. While it can be theorized as behavior in response to physiological and biological demands, dieting is also an intersubjective phenomenon. From a sociocultural reading, we perceive it as behavior aimed at obtaining a historically built ideal under the

influence of different culturally expressed forces, such as the media and science. In this sense, as discussed here, dieting can be characterized as an instrument open to different meanings based on established perspectives and the subject’s relationship with the world. Finally, for such a redefinition, we believe that it is essential to be sensitive to new perspectives and open to dialogue, understanding the limits within which this concept is included, such as those that delimit dieting to the expectation of unrealistic results, in order to traverse it through a reflective process, thus expanding the possible links to the term.

Intersectionality · Humanism · Posthuman

Disability oftentimes tends to be associated with misfortune, personal tragedy, passivity, and dependency. However, a closer look at the actual history of the disabled people's movement and disability studies reveals stories of imagining disability and therefore societies differently. The lineage of envisioning the world through the prism of the possible (rather than impossible) is not complete without including the theorization and politicization of disability – that in the past few decades has gained intellectual momentum. In the following paragraphs, we map the most critical turning points in those academic and activist developments.

Disability Studies as an Academic Counterpart of the Disabled People's Movement

In the 1970s, the British group of disabled people, the Union of the Physically Impaired Against Segregation (UPIAS), contributed hugely to changing the dominant paradigm in thinking about disability, a dominant view that framed it as a medical and individual problem. In a manifesto from 1976, they announced that it was not individual bodies but society that was responsible for the production of disability. In “The Fundamental Principles of Disability,” they defined disability as a phenomenon caused by social conditions and one that can and should be changed (UPIAS 1976, p. 4). Introducing the distinction between

disability and impairment, they postulated that the reason for the unequal status of people with disabilities is not related to their innate limitations, but physical and social barriers that impede their participation in various areas of life. A social approach to the study of disability becomes a tool for understanding and contesting discrimination, isolation, and oppression of people whose bodies and minds deviate from strictly defined sociocultural norms as well as those associated with health rather than illness. In this approach, disability is becoming not a medical category, but a political one.

In the early 1990s, disability studies founded on the tension between medical and social views of disability started to become part of academic institutions. Disability studies are located between scientific reflection and social and political activism, where they play a critical role (pointing to oppression, seeking legislative changes and changes in social attitudes, and emancipation, linked to the activism of disabled people and their allies). Disability studies investigate the injustice and oppression of people with disabilities – nowadays and in a historical perspective – to show the paths for the future but also bring disability issues out of the closed circle of medicine, rehabilitation, and social assistance.

Activists' and Academics' Encounters: Social Model of Disability

The UPIAS approach toward disability was termed in 1983 by Mike Oliver, first professor of disability studies, as “the social model of disability.” This notion over became central for disability studies and disabled people's movement (Shakespeare 2006). However, Oliver was not introducing a new idea, per se, but, as he himself stressed, took this division “quite simply and explicitly from the distinction originally made between impairment and disability by the Union of the Physically Impaired Against Segregation” (Oliver 1990). Oliver treated the social model as a “practical tool” (2004, p. 30) which he defined as follows:

[n]othing more or less fundamental than a switch away from focusing on the physical limitations of particular individuals to the way the physical and social environments impose limitations upon certain groups or categories of people (Oliver 1983, p. 23) and thus excludes them from mainstream of social activities. (Oliver 1996, p. 22)

Oliver's definition of the social model of disability, with its stark division between impairment and disability, enhanced the materialist perspective in regard to identifying and examining disabling conditions that disabled people face in societies – and therefore has been referred to as the “strong social model” approach, while prominent disability studies scholars who adhered to it were labeled as “strong social modelists” (Shakespeare and Watson 2001). One of these social modelist academics, Colin Barnes, explained that the social model is to function in disability research and interrelated disability advocacy and politics as “a tool with which to gain insight into the disabling tendencies of modern society, in order to generate policies and practices to facilitate their eradication” (2003, pp. 6–7). Indeed, the social model of disability triggered a wealth of knowledge-making and meaning-making that addressed disability (Goodley et al. 2012; Roulstone et al. 2012) and in effect revealed and challenged material, environmental, and cultural barriers as well as prejudices, stereotypes, and oppression, permeating capitalist societies (Meekosha and Shuttleworth 2009). Contesting hegemonic disability models and interrelated narratives and/or representations of disabled people with the means of the social model informed disability advocacy and politics – some of which was successful in tackling structural barriers (Morris 1991; Roulstone et al. 2012) and brought a stronger sense of empowerment and dignity for disabled individuals (Morris 1991). Specifically, the social model of disability has served as one of the foundational ideas of the Convention on the Rights of Persons with Disabilities (UN 2006), which definitely frames disability as a human rights issue. For disabled people around the globe, the Convention is associated with “new possibilities” in regard to making

their lives “better.” Moreover, the Convention imposes on states the obligation to collect data necessary to implement the provisions of the Convention in practice. Thus, statistics and data collection clearly play a service role toward the rights and freedoms that CRPD postulates. They are to provide information necessary to monitor the situation of people with disabilities and to implement policies and activities that support equality and equal opportunities for people with disabilities in various areas of life.

Feminist Disability Studies

Feminist disability studies were developed at the intersection of disability studies and the feminist and disabled people's movement (Garland-Thomson 2004). American, British, and Canadian disabled women activists, writers, artists, and researchers who in the 1980s started on an unprecedented scale of publishing works problematizing the situation of disabled women in their societies and cultures are considered the forerunners of this academic orientation (Szarota 2019). As they stressed they were disappointed that otherwise flourishing women and disabled people's movements have overlooked the discrimination of disabled women and on top of that were also found guilty of discriminatory practices against representatives of this group that in turn limited their activist and/or research engagements. Rebecca S. Grothouse expressed that sense of urgency as follows: “[d]isabled women must demand our rights, because waiting for someone else to do it hasn't worked out yet” (Grothouse 1985, p. 128). Despite their disillusionment with the mainstream feminist movement, they adopted its core premise of the “personal is political” to theorize lived experiences of disabled women. On the basis of this approach, the literary and scholarly publications from the 1980s and 1990s established a thematic canon for feminist disability studies which includes issues such as stereotypes and prejudices, education, employment, representations of disabled women in culture, reproductive rights and sexuality, parenthood and motherhood, care, (de)

institutionalization, violence, impairment versus disability, illness as disability, disabled embodiment, and aging (Bê 2012; Szarota 2019). While feminist disability studies' aims are to tackle the discrimination of disabled women and contribute to their economic, sociopolitical, and cultural emancipation, its focus is also broad. As one of its key scholars, Rosemarie Garland-Thomson explains:

[feminist disability studies] is more than research and scholarship about women with disabilities, just as feminist scholarship extends beyond women to critically analyze the entire gender system. Like feminist studies itself, feminist disability studies is academic cultural work with a sharp political edge and a vigorous critical punch. Feminist disability studies wants to unsettle tired stereotypes about people with disabilities. It seeks to challenge our dominant assumptions about living with a disability. It situates the disability experience in the context of rights and exclusions. It aspires to retrieve dismissed voices and misrepresented experiences. It helps us understand the intricate relation between bodies and selves. It illuminates the social processes of identity formation. It aims to denaturalize disability. In short, feminist disability studies reimagines disability. (2004, p. 1557)

Therefore – while feminist disability scholars draw upon the social approaches to disability (including the social model) – they have expanded it theoretically and empirically and in doing so shed new light on the nature of disablement as well as provided new ways to tackle it.

Disability Studies: Epistemology and Methodology (Case Studies: Intersectionality and Participatory and Emancipatory Research)

The transformation of the disability model from the medical/individual to the sociopolitical and human rights, the development of civic aspirations, and the work of activists with disabilities led to paradigmatic changes in disability studies (Goodley 1998; McVilly and Dalton 2006) and also highlighted the discrepancy between social discourses and research rhetoric, forcing researchers to think about ways to study disability.

The topic of disability has been raised for years by researchers, and at the same time, disabled people often have had the feeling that regardless of the field, they are talked about and written off as patients or dehumanized research objects. The reason for this is still the dominant analysis of various aspects of the lives of people with disabilities from the perspective of other people: carers, therapists, teachers, or service providers. This leads to a situation in which the issues undertaken by researchers are not always important for the interested parties themselves – people with disabilities – especially in a specific sociocultural or situational context, and the conducted research does not necessarily bring measurable benefits to the persons concerned.

The answer to the criticism of the monopolization of knowledge by the army of “experts” has been the participatory paradigm (Heron and Reason 2001). It assumes that, in order for scientific research to provide important foundations for optimal organization of living space for people with disabilities, it should take into account their voices and involve the interested parties themselves. Participatory research is a two-way exploration. The first one, based on the traditional role of the research subject, engages interested parties themselves and uses methods that create the possibility of activating people with disabilities and reaching the knowledge important for them. The second one is that people with disabilities take on nonstandard roles and appear as advisors and consultants as well as co-investigators with varying degrees and scope of involvement and decision-making and executive participation in the research process (e.g., Bigby and Frawley 2010; Garcia-Iriate et al. 2009; Traustadóttir 2001; Wołowicz 2018). The key importance of a participatory approach in scientific research is expressed in obtaining knowledge that reflects the subjective perception of reality and its meanings and assessments from the perspective of the needs and possibilities arising from the disability itself.

A unique and innovative example of research in the participatory paradigm is the inclusive research which involves people with

intellectual disabilities¹ in the roles of researchers. In this proposed research model, people with intellectual disabilities are not treated as static and passive from the point of view of the dynamics of the research process, sources of knowledge, where the subject faces ready-made research assumptions, having generally completely no influence on the course of the research process. In the inclusive research model, people with intellectual disabilities are involved in developing issues and research concepts, conducting research, analyzing the material obtained in order to search for the meanings arising from it, co-creating theories, and disseminating the results (Goodley and Moore 2000; O'Brien et al. 2014). The position of the respondents defined in this way is a consequence of the recognition of their competence as subjects of their own activities and experts in their own affairs. The strategy of including representatives of this group as co-investigators is still underway, as well as an attempt to describe ways to maximize their participation and control at every stage of the study. How to disclose their competences in the research process and how to protect their autonomy and agency are also discussed (Abbot and McConkey 2006; Walmsley 2001). Inclusive research contributes to overcoming stereotypes assuming the lack of self-awareness of people with intellectual disabilities, lack of orientation in reality, and the inability to assess it. This research is important in strengthening the understanding of intellectual disability as a social construct, showing the ambiguity of the meaning of reality from the perspective of people with disabilities. Inclusive studies also show the diversity of the population of people with disabilities.

Within disability studies, disability is not a universal, unambiguous, and invariable phenomenon but a concept that, as emphasized by the Convention on the Rights of Persons with Disabilities, is constantly evolving. The medical model of disability contributes to a consolidation

of thinking about people with disabilities as “medical cases,” assuming that all the difficulties they experience are only the consequences of illness or damage to the body (Barnes and Mercer 2004). Therefore, disability in this model is not only a differentiating feature but also a negative one. In order to overcome research limitations in social sciences and analyses of sociocultural diversity, the concept of intersectionality has been proposed, which is the result of attempts to theorize difference and reflect on how to value and incorporate diversity into the social context not as negative or problematic phenomenon (Hill Collins 2009).

Threads related to the ways in which identity and belonging to various groups are intertwined and the impact of this belonging on life opportunities were first raised by American feminist activists in the 1970s. At that time, postulates for building a social order in which women's possibilities and aspirations would not be perceived in one dimension, i.e., only through the prism of gender, were developed. Nevertheless, at the end of the 1970s, some feminist activists began to pay attention to the fact that feminism postulations do not always take into account the perspectives and experiences of women perceived as socially “other” – with ethnic identities other than white, from lower classes, with lower education or income. Thus, they showed that many characteristics, identities, and belonging decide about the human situation. Following this lead, Kimberlé Crenshaw, an American researcher, introduced the concept of intersectionality to her scientific work in the late 1980s (Crenshaw 1989). At present, intersectionality is understood as an approach analyzing the ways in which social and cultural categories intersect, overlap, and strengthen one another. Adopting the perspective which says that activities for people with disabilities should take into account knowledge of the specifics of their functioning also due to gender, age, sexual orientation, migrant status, and other premises allowed to see this group as internally diverse and more effectively study the parts which do not fit into the privileged group within the minority (Knudsen 2005; Wołowicz-Ruszkowska 2015).

¹ Intellectual disability is a developmental disorder characterized by a decrease in the general level of intellectual functioning and deficits in adaptive behavior.

Affirmation and Capacity Perspectives

Affirmation is at the heart of the politics of disability. The very acts of disability activists are, at their very essence, the affirmation of disability as a productive entity and the celebration of the lives of disabled people. This double affirmation (1) posits disability as an aspect of the human condition to think differently about the world and (2) positions disabled people as political activists with much to contribute to the current political commons. Let us take each of these affirmative moments in turn. To suggest that disability is a phenomenon, an experience, a lifeworld, or an ontology to rethink our relationships in the world is a provocation offered by disability studies. An example of reframing is given by Tim Booth and Wendy Booth (1994, 1998) and their pioneering work on the lives of parents with intellectual disabilities. Their disability research worked closely with the lives of these parents to capture many of the challenges they faced in parenting their children. These challenges were often associated with the barriers they faced, as new parents, from professionals such as social workers who already had in mind the assumption that parents with the label of intellectual disabilities were psychologically incapable of looking after their children. This assumption should not be understood as a prejudice endemic within the social work profession because social workers are inherently negative human beings. Instead, Booth and Booth found that a deficit perspective was ripe within social work because of the commonly held view (a view that abounds even today across our society) that having an intellectual disability equates with incompetence to parent. Social workers, then, translated this deficit thinking into their practice and were more likely to find parental incompetence precisely because they were expected to find it in the parenting of adults with intellectual disabilities. In contrast, they found, were one to adopt a capacity perspective to social work practice – to assume that parents can look after their children with the right kinds of support network around them – then parents (and their children) were more likely to benefit from this kind of professional input. Booth and

Booth (1998) developed the concept of distributed parental competence. This idea assumes that strong kinship and community support networks provide the necessary conditions to support and empower parents in their daily lives with their children. Indeed, the very presence of intellectual disability and the community's knowledge of this phenomenon, in a number of their research case studies, led to a variety of rich, supportive, and empowering support networks that supported the families. Intellectual disability has the potential, then, to provoke an affirmative community response. Disability elicits capacity perspectives. This leads us to the second point of affirmation: the contributions of disabled activists. In my 1998 book, I found that people with intellectual disabilities were involved in a rich politics of resilience (Goodley 1998). Since the 1960s, people so-labeled have been engaged in the self-advocacy movement, a global political movement that fights for the political recognition of people with intellectual disabilities. Drawing on slogans such as "Label Jars Not People" and organizing under the title of "People First," people with intellectual disabilities have demanded that we not only recognize their ambitions and aspirations but also question the potentially damaging consequences of sticky labels such as intellectual disabilities. This is not to deny the presence of intellectual disability, though it is to question the dehumanizing impact of its application. This is but one example of the affirmative qualities associated with work of disability activists.

Humanism and Disability Theory

The preceding section's discussion of disability's affirmative potential leads us neatly into a discussion of humanism. Clearly, the self-advocacy of people with intellectual disabilities is evidence of a fight to be recognized as full human beings. Such a fight is understandable. When others assume that your competence is compromised by your disability, then it makes complete sense to want to contest such dehumanizing assumptions. Disability politics has, therefore, had a long engagement with humanism. This philosophical

position reflects, according to Rosi Braidotti (2013, p. 29), a legacy of the enlightenment, forever associated with cherished notions of autonomy, responsibility, self-determination, solidarity, community-bonding, social justice, and principles of equality. To reposition oneself as autonomous and responsible – as a parent with intellectual disabilities – is to appropriate humanism in order to reconfigure oneself as a human being that it is fit to parent. To re-establish oneself as *People First* is to demand recognition of one's humanist essence as an individual; an individuality often lost when one is associated with the label of intellectual disabilities. Moreover, the United Nations Convention on the Rights of Persons with Disabilities is a supranational discourse that plays out across the world from Dubai to Delhi. Humanism continues to undergird much of what we understand in terms of human rights and the pull toward processes of rehumanization: especially in the case of those human beings who have been historically cast as less than human. To draw on the language of humanism is to seek reintegration into the human category, for after all:

[n]ot all of us can say, with any degree of certainty, that we have always been human, or that we are only that. Some of us are not even considered fully human now, let alone at previous moments of Western social, political and scientific history. (Braidotti 2013, p. 1)

Disability studies and disability politics contribute toward the project of what Paul Gilroy (2018) calls a “re-enchantment with humanism.” And this project hails in a critical encounter with how the human category has been constituted, in ways that include or exclude certain kinds of human being.

Posthuman Disability Studies

For some disability scholars, the desire for disability to be recognized by the humanist register is one that needs to be resisted. The reasoning behind this resistance can be found in this question: why would anyone want to be recognized by a way of thinking that has historically erased oneself? Humanism is, for some critics, inherently

exclusionary because it already has in mind a preferred model of humanity (as an autonomous, independent, and self-sufficient soul) that many humans fail to match up to. Why, then, would one want to embrace humanism if one is going to be rejected by this way of thinking? This denunciation of humanism has led scholars to engage with posthumanism (e.g., Feely 2016; Flynn 2017; Goodley et al. 2014, 2018; van Trigt et al. 2016). The work of Rosi Braidotti has been central to the development of this perspective, and it seems only right to offer a partial definition of post-human thinking to her:

I define the critical posthuman subject within an eco-philosophy of multiple becomings, as a relational subject constituted in and by multiplicity, . . . a subject that works across differences and is also internally differentiated, but still grounded and embodied. Posthuman subjectivity expresses an embodied and embedded and hence partial form of accountability, based on a strong sense of collectivity, relationality and hence community building . . . an affirmative bond that locates the subject in the flow of relations with multiple others. (Braidotti 2013, pp. 49–50)

In contrast to the individually bounded autonomy associated with the humanist subject, the posthuman subject emphasizes distribution, relationality, and collectivity. The posthuman condition is one in which we all find ourselves relationally distributed across virtual and real connections between humans and nonhumans. A child living in Manchester, England, for example, is a global child, touched by the Internet, governed by supranational and national educational policies, plugged into a host of virtual environments, located in a local community increasingly influenced by the pan-national. And, as Goodley et al. (2014) have argued, disability is in many the quintessential posthuman subject. It is possible, therefore, to position disability politics and the lives of disabled people in a posthuman milieu precisely because these politics and ways of living are extended and distributed. Hence, the parenting and self-advocacy of people with intellectual disabilities can be reread as evidence of productive posthuman interdependencies, relational connections, and affirmative community networks. By moving into

the posthuman register, we bypass the narrow humanist conceptions of humanity as autonomy and, instead, consider the ways in which the politics of disability feed positively into the posthuman condition in ways that enrich the lives of disabled people and those around them. Moreover, disability is positioned not as the absence of humanity but a phenomenon from which to think together about the posthuman contemporary moment.

Discourse

Mirko Demasi

Leeds Beckett University, Leeds, UK

Abstract

“Discourse” is a word that one comes across frequently. It finds a home in empirical research and media alike, but it is a term that is not always clearly defined. This entry will offer one way that one can understand discourse, that is through the lens of discursive psychology. The overarching argument is in favor of an expansive understanding of the possibilities of studying discourse: If it can be uttered, written, or expressed in another format then it can be empirically researched. Through an appropriate analytic lens, it is much more empirically and materially tangible than is often appreciated. The first part covers what a discursive psychological understanding of discourse entails, and a short explanation of what discursive psychology is. The second part is an overview of various contexts where discursive psychology has contributed to the study of discourse. In the final section I briefly discuss some possible areas – so far relatively absent in discursive research – of study using a discursive approach, particularly in the context of studying the discursive construction of deductive logic.

Keywords

Discourse · Discursive psychology · Possible · Science · Deduction · Logic

Introduction

This entry is going to be divided into two parts. In the first part, I provide a brief overview of the body of discursive psychological work on discourse. However, the reader should not infer from this a primacy of discursive psychology or that it be the only way to study discourse. In line with the encyclopedia, my aim is to show *possible*

ways to study discourse rather than provide a comprehensive overview. The reader should note that this is going to be a necessarily short and possibly an unjust overview of a vast body of work. My choice of focusing on discursive psychology is a simple one. As a social psychologist who uses discursive psychology this is the area of discursive studies that I am most familiar with. However, discourse is studied from a wide range of academic subjects and there are a multitude of different ways to analyze it depending on where one comes from academically. For example, one can study discourse using the following approaches: conversation analysis, critical discourse analysis, critical discursive psychology, discourse analysis, discursive psychology, multimodal/embodied conversation analysis, rhetorical political analysis, rhetorical psychology, and (some variants of) thematic analysis to name a few. The way one studies discourse can be heavily influenced by one's academic background.

In the second part I will look at some of the possibilities that the topic of discourse, and the body of discursive research, can contribute to scholarly work. Although I will list a number of possibilities, I have chosen a particular theme to go into more detail that, to my knowledge, has not been explicitly looked at so far: the discursive construction of scientific argument.

Overview of Discursive Psychological Work

Before moving on to discussing the various bodies of research focusing on discourse, it is beneficial to provide a rough overview of what I mean to be discourse as understood in discursive psychology (henceforth DP). Potter and Wetherell (1987) introduced discourse as an entity that does not have a neat definition, it varies depending on discipline and method of analysis. They follow suit from Gilbert and Mulkay (1984) and conceptualize discourse as something that includes “all forms of spoken interaction, formal and informal, and written texts of all kinds” (Potter and Wetherell 1987, p. 7). Not all forms of analyzing discourse adhere to this view. For example,

conversation analysis (CA) leans itself more toward what it refers to as “naturally occurring interaction” – data that passes the dead social scientist test¹ – whereas a more critical, Foucauldian, approach to discourse analysis will take discourse to include and be included in a much wider range of practices. For this entry I will work with the definition offered by Potter and Wetherell (1987), though with an added understanding, which should become apparent later on due to its wide applicability, namely that “discourse” should be understood as all forms of speech, text, and image. My understanding of discourse is that it entails *all* forms of conveying action and meaning, of which language-based communication (i.e., speech and text) are some of the more sophisticated and analyzable aspects, but by no means the only ones.

DP draws its origins from three works in particular: Billig (1987), Edwards and Mercer (1987), and Potter and Wetherell (1987), culminating in the book *Discursive Psychology* (Edwards and Potter 1992) which, to this day, remains one of the primary texts for becoming familiar with DP. These scholars began a body of work that took a radical departure from the existing standard of psychological research of their times, especially regarding the role of speech and language. In so doing they offered a critique of mainstream psychology, and in particular its cognitive variants. The nub of this critique is that one cannot use language to infer thought (Edwards and Potter 1992) in the way much of existing psychological literature has done. Instead, they offered an empirical alternative by looking to *discourse as a site where psychologically relevant action unfolds*. In this sense, discourse becomes a prime phenomenon worth studying on its own terms, rather than treating it as a mere conduit, or a proxy, for other phenomena. This has resulted in a systematic re-specification of psychological notions (Huma

¹“Would the data be the same, or be there at all, if the researcher got run over on the way to work?” (Potter 2002, p. 541). In other words, for the data to pass this test its existence needs to be independent of the researcher's actions.

et al. 2020). One can use DP to fundamentally challenge the interpretation of findings in well-established psychological research which, in turn, questions our very understanding of basic psychological concepts. For example, Gibson’s (2013, 2019) work on looking at the interactions in the well-known obedience experiments run by Stanley Milgram (1963, 1974) has given us a new way to understand the concept of obedience. In his close analysis of the recordings of Milgram’s experiments, Gibson makes a number of important observations. First, he shows that the prods were not delivered in the strict order in which they were reported. This does not detract from the value of Milgram’s work, but highlights that there may be a discrepancy between how standard scientific reporting is done and how the actual experimental interactions unfold. This distinction is very important. Second, because the actual interactions are more intricate than reported suggests that something more complex is going on. Looking at the interactions, Gibson (2013) argues that we should reconsider how we understand obedience. In practical terms, obedience is much more indirect, argumentative, rhetorical, flexible, and varied than conventional psychological research would suggest. One might understand obedience in a more contextual and practical manner, rather than treat it as a behavioral compliance to a direct order. Gibson argues that

any analysis that purports to present a complete account of dis/obedience but which fails to conceptualise the active rhetorical nature of language use is inherently limited, and moreover risks breaking down when specific instances of dis/obedience are scrutinised. (2013, p. 307)

Our appreciation of the practical complexity of social psychological phenomena, in this instance obedience, is due to looking at discursive practices.

A classic and enduring critique is to question the use of questionnaires as a way to empirically study attitudes (Potter and Wetherell 1987). A DP approach would argue that attitudes could be understood as occasioned and varying depending on the context (Billig 1989) and made sense of as evaluations that draw their function and meaning

from being embedded within discourse, (Potter and Wetherell 1988). That is, one cannot readily understand attitudes as abstract entities that are somehow stable and empirically tangible via standardized quantitative methods that treat language as evidence of cognition. According to DP, attitudes are rendered *qua* attitudes *in and through* discourse. The main analytic points of focus of DP can be found in the discursive action model (DAM) (Table 1).

If the reader wishes to read more about this, the works of Edwards and Potter (1992), Potter (2012), and Wiggins (2017) can provide a thorough and accessible overviews. There tends to be a general trend of four types of DP (Potter 2012; Wetherell and Edley 2009) including first, the study of interpretive repertoires; second, a focus on naturalistic interactions; third, a sequential analysis of discourse heavily influenced by CA; and fourth, a critical DP, with a closer alignment with critical discourse analysis (CDA).

DP covers a wealth of various topics and modes of analysis. Examples include mealtimes and how food preferences are embodied in

Discourse, Table 1 DAM (Edwards and Potter 1992, p. 154; 1993)

<i>Action</i>
1. The focus is on action, not cognition
2. Remembering and attribution become, operationally, reportings (and accounts, descriptions, formulations, versions, and so on) and the inferences that they make available
3. Reportings are situated in activity sequences such as those involving invitation refusals, blamings, and defenses
<i>Fact and interest</i>
4. There is a dilemma of stake and interest, which is often managed by doing attribution via reports
5. Reports are therefore constructed/displayed <i>as</i> factual by way of a variety of discursive techniques
6. Reports are rhetorically organized to undermine alternatives
<i>Accountability</i>
7. Reports attend to the agency and accountability in the reported events
8. Reports attend to the accountability of the current speaker’s action, including those done in reporting
9. The latter two concerns are often related, such as 7 is deployed for 8, and 8 is deployed for 7

discourse (Wiggins 2014), advice giving and its delicate delivery (Hepburn and Potter 2011), health interaction (Burke and McGeechan 2020), political debates (Demasi 2019; Demasi and Tileagă 2019), political speeches (Edwards and Potter 1992), online discussion forums (Børlie and Goodman 2021; Meredith and Richardson 2019), repressive silence (Murray 2021), social media (Burke 2018; Burke et al. 2020; Snejder et al. 2021), broadcast programs (Carr 2021), and police interrogations (Stokoe and Edwards 2007, 2008).

One can use these topics to understand matters of emotion (Edwards 1997, 1999), identity (Antaki and Widdicombe 1998), prejudice (Augoustinos and Every 2007; Burke and Demasi 2021; Billig 1988; Tileagă 2016), attitudes (see above), to explore how the inner psychological life is displayed in an embodied manner (Wiggins and Osvaldsson Cromdal 2021), and other psychologically relevant material.² This is part of DP's move to re-specify psychological concepts to demonstrate how we make sense of psychological phenomena as a practical matter. Alternatively, if one is concerned about how to analyze discourse in various contexts, then one can tap into the diverse body of work that looks at discourse in different contexts: mundane interaction, interviews, multiparty interactions, heated arguments, online chat forums, multimodal analysis, media more broadly, and so forth. Or one can use DP to explore various dimension of discourse as it unfolds³: extreme case formulations (Pomerantz 1986), overlapping talk (Schegloff 2000), displaying and managing "knowledge" (Heritage 2013), and so forth.

Within the more specific domain of political communication, DP has had a long history since its earliest days (see examples in Edwards and Potter 1992) to the present day (Demasi et al. 2021). For example, rather than treat "facts,"

such as statistics, as mere reflections of an underlying reality, their rhetorical nature is worth exploring (Billig 2021; Demasi 2019) to appreciate the discursive *action* related to facts: "constructions of facts are not neutral reflections of an objective reality; they are rhetorical means to rhetorical ends" (Demasi 2019, p. 18). A diverse range of different topics have been explored within the domain of political communication: extreme prejudice (Billig 2001; Burke and Demasi 2021), accusations of prejudice (Gibson 2021; Goodman and Burke 2010), denials of prejudice (Augoustinos and Every 2007; Byford 2006), conspiracy theories (Byford 2011), public accountability (Tileagă 2010a, b), political cartoons (Lennon and Kilby 2021), parliamentary discourse (Figgou and Anagnostopoulou 2021), blogs (Pettersson and Sakki 2021), lay understandings of politics (Andreouli 2021), and social and national identities (Abell et al. 2007; Condor 2000). My recent work (Demasi et al. 2021) is a summary of the various types of political communication that one can study using DP.⁴ What should be clear is that even within this particular analytic tradition of discursive psychology, the body of discursive work is a very broad church.

Discourse and Science

This leads us to the following question, and the crux of this encyclopedic entry, what is possible within the realm of discursive studies? Two particular possibilities arise: a methodological discussion spurred on by the existence of research that looks at discourse *as* discourse, and this possibility has been in the process of being consummated since the early days of DP, and how, because of this debate, one can explore the discursive construction of scientific arguments.

Discursive psychology is an example, par excellence, of a *counterinductive* (Feyerabend 2010) approach. Not only has DP developed its own interpretive framework and its own

²Or, as Edwards and Potter (2005, p. 241) say, the "psychological thesaurus."

³This dimension of DP is closely aligned with CA, and the disciplinary boundary here is more blurred. Hence the citations here are from conversation analytic work, but bear relevance for DP.

⁴For an overview of various traditions of studying political discourse, see Condor et al. (2013).

terminology, distinct from standard practices of psychological research, but, additionally, is also a form of critique of the fallibility of what we hold to be sound scientific, quantitative, and positivist practice. Due to this position, practitioners of DP argue in favor of a systematic empirical alternative. This approach highlights the place of discourse at the center of our social and cultural lives; it mediates everything we do, from exchange of knowledge (whether in talk-in-interaction, science, conspiracy, politics, etc.) to the most banal forms of social action (inviting a friend for lunch, greetings, asking for a cup of tea, etc.). Indeed, discourse is what unites all diverse forms of human life – it provides a link from the highly abstract to everyday life. This means that it is important to study discourse in its various concrete aspects and not to treat it as a mere proxy for more abstract notions, whether these are concepts, cognitions, or something else.

It is *possible* for each subject to have a discursive component. Indeed, we can argue that since it is possible to study discourse in all aspects and contexts of its mediating role as we communicate as individuals, as groups, as societies, its place in and across academic disciplines is becoming more significant and influential. Each discipline has room for an empirical study of its relevant discourse(s) and its relationship to the discipline.

A Way Forward

I would like to suggest further possible avenues of research and consideration. Ludwig Wittgenstein's (2010) later work suggested we look at the communal functions of language, and how we might understand it. This philosophical turn has had major implications and is one of the earlier influences of what is called discursive psychology today, as well as paving the way for many other disciplines too. We might consider whether we can turn this discursive attention in another direction. Wittgenstein's philosophy of language eventually turned into a new empirical study of discourse; why not turn this new empirical study of discourse back to philosophy of science? Namely, the rhetorical

construction of philosophical arguments, especially in the case of deductive and inductive arguments, foundational as they are for argument and enquiry. I will very briefly discuss some possibilities.

First part of the strength of a deductive argument resides on the premises being true. One can deduce effectively *if* the premises are true. Yet this "if" can have a rhetorical dimension of being a tiny adjunct that might not receive attention, and so quickly glossed over. However, in practice this "if" can speak volumes. Combine this with the notion that an appropriate deduction contains the conclusion in the initial premise. Now, we can begin to analyze deduction as a form of discourse and note that philosophical argumentation is required not only to "find the truth" but also to rhetorically argue for a proposition. By recognizing its rhetorical nature, by *understanding deduction as a form of discourse*, we can see how deductions, and philosophical thought (even a strictly positivist one), do not exist in a vacuum. If facts are ideological, as Feyerabend (2010) argues, then we must view deduction, too, as an ideological proposition based on a particular way of determining premises. This has serious implications to how we view the place of deductive arguments, especially when dealing with abstract notions. Because abstract notions are studied often via proxies, such as treating speech as evidence of thought (Billig 2009), this means that one has to rhetorically, in and through discourse, construct this link and *construct it as true*. Because questions and answers are inevitably paired, it stands to reason that when one is deducting with abstract notions one is always bound to find an answer. And one that conforms to the scientific pressures of the time, unless one is prepared to think (argue through discourse) non-scientifically in order to advance science (Feyerabend 2010). At first glance the pairing of a question and answer in deduction may strike one as a banal observation, however it raises a serious point. This means that it becomes difficult to disentangle between one's answer from the mode of reasoning (deduction) and the available empirical data. The focus on the discursive construction of deductive reasoning may alleviate the

many discussions around the replication crisis that psychology finds itself in today.

Second, Edwards (2012) suggest that a significant benefit of DP includes the notion of a reduced interpretive gap. He defines it as “the distance between the object under scrutiny and, via method, data processing, and inferences, what you eventually want to say about it” (p. 428). This stands in contrast to a method of enquiry, in his case cognitive psychology, where one deals with discourse as a proxy rather than an object of study in and of itself. His concept has a wider utility. One can use that to look at the rhetorical construction of scientific and philosophical arguments. For example, how might one downplay an arguably large gap in order to advance a particular line of argument? To return to the example of cognitive psychology, this gap is large and its treatment of language-as-a-window-to-cognition is an axiomatic premise. This discursive construction invites not only a close discursive analysis (as has been carried out in science by Gilbert and Mulkay 1984) of scientific and philosophical discourse, but, in addition, an investigation of academic and scientific practice.

Third, following on from this, Billig (2009, 2013, 2019) has been critical of the way empirical psychology is written and used in academia. In particular, he criticizes how technical language can mask the matter of human agency in discourse. He argues in favor of a more “populated” social psychology that rightfully portrays people as doing the doing – agency is recognized by talking about who-does-what over how a particular psychological or discursive process might unfold. The suggestion is for a more holistic approach that explores the place of discourse, especially when arguing for particular ways of knowing the world, both in the philosophy of science and in the construction of empirical arguments. For example, we could look at the discursive construction of empirical arguments to explore our conceptual understanding of ontological and epistemological questions. It would benefit the academic community if there was a systematic study of the discursive construction of forms of scientific ideology. What do we treat as an explanation? Are some explanations treated

as more foundational than others? Why? How does one discursively construct a case for this? How does one treat something as not an explanation? In particular it is worth asking what are the arguments, if any (for silence can be an argument), of materialist approaches in science being treated as more “real” than non-materialist approaches? We could look at the discursive and rhetorical constructions of such arguments to explore this further. How are physics justified to be the most common philosophical starting point of ontological questions? Crucially, what are the philosophical and methodological implications of a model that assumes a mechanistic cause-and-effect relationship – especially in terms of variables – that might easily have a role to play in arguments regarding free will? This we do by examining the discursive and rhetorical constructions of philosophical and scientific principles.

These suggestions potentially highlight that philosophy of science arguments are constructed *discursively*, as is every form of interaction. Just as one can construct discourse of any kind, this means that one can construct any deductive or inductive argument and so become a creative enterprise in order to be able to “think outside the box.” This becomes possible especially when we are prepared to tolerate nonconventional ways of making scientific arguments.⁵ Not as an excuse for poor quality work or poor thinking, but by appreciating the discursive nature of reasoning as something that can expand our ability to view scientific and philosophical questions. For example, should one choose to use a different discursive construction for the human mind than the cognitive one, couching it in different discursive terms, this could give a very different understanding of how we view, conceptualize, study, and understand how we think and understand ourselves and others. I refer to cognition here as a computational metaphor for thought. The argument here is that we cannot directly observe thought or cognition, saved within a discursively

⁵Non-standard as understood by Feyerabend (2010) and Kuhn (2012), whose critiques of “science,” in their cases, more specifically referred to the orthodox way of doing science.

constructed theoretical framework that will axiomatically treat specific phenomena as observations, or possibly evidence, of cognition. The various cognitive frameworks and their theoretical underpinnings are just one group of discursive means of making sense of psychological phenomena.

One line of alternatives can already be found in understanding thought to be a dialogical and argumentative process (Billig 1996; Linell 2009; Marková 2000). This means, briefly, that thought is conceptualized in a more discursive manner; one can observe thought when people speak of complex issues (“on the one hand... on the other hand”) and acknowledging the possibility that one might also debate with oneself (Billig 1996). What other ways can we use to understand the mind? This diversity, and its discursive potential, is to be celebrated with a plethora of possibilities to go forward to explore the many facets of scientific, academic, and philosophical thought and practice, as realized in and through discourse.

Dishonesty

Andrea Pittarello¹ and Daphna Motro²

¹Psychology Department, Virginia Tech, Blacksburg, VA, USA

²Frank G. Zarb School of Business, Hofstra University, Hempstead, NY, USA

Abstract

Dishonesty can be broadly defined as any behavior that violates what most people deem acceptable or that breaks the rules. While initially confined to clear violations, such as cheating and stealing, research now also considers lack of reciprocity, failure to restrict energy consumption, and exploiting loopholes as dishonest behaviors. Given the breadth of these behaviors, scholars from psychology and neighboring fields have developed novel theoretical and empirical approaches to understand what drives good people to do bad things, and what can be done about it. This entry is not limited to a review of this literature. Rather, it discusses some of the processes in which dishonesty can make “*the impossible possible*,” such as bending the rules while feeling honest, unconsciously lying to ourselves, seeing reality in self-serving ways, and even promoting creativity. It will conclude with the discussion of some current research on how dishonesty can be curbed in real-life settings.

Keywords

Dishonesty · Justifications · Unethical behavior · Morality · Decision making

Introduction

When thinking about dishonesty, some may imagine students cheating on a test or job candidates lying on their resumes. Some can recall a catastrophic business scandal or the untrustworthy behavior of a salesperson. Or others can think about the daily lies people tell others (DePaulo and Kashy 1998), some of them “white lies,”

while others out of spite (Gneezy 2005). Given the many ways people think about what is dishonest it is difficult to clearly define dishonesty. Accordingly, researchers use dishonesty as an umbrella term that covers unethical behaviors such as cheating, stealing, fraud, deception, and other questionable acts. Over time, each of these behaviors has developed its own empirical and theoretical line of research. However, the purpose of this entry is not to list and review the key findings of these fields, nor to describe how they differ from each other. Rather, it aims to provide a definition of dishonesty based on prior literature and to illustrate how dishonesty can make the “impossible possible.” This could be by changing how people interpret their actions, beliefs, the way they process information, and even by promoting desirable behaviors.

Dishonesty is defined as a decision that is either “*illegal or morally unacceptable to the larger community*” (Jones 1991, p. 367). But *how* do people decide whether to behave dishonestly or not? *How* do they determine what is morally acceptable? A first attempt to model dishonest behavior stems from the work of Gary Becker (1968) and his normative approach to crime. The idea is that the decision to break the rules depends on the trade-off between the costs (the probability of getting caught and the punishment) and the benefits (e.g., more money, a higher status) of doing wrong. Simply put, an agent would likely engage in dishonest behavior if and only if the benefits outweigh the costs. Note that this “economic approach” is a *method* of analysis: It neither makes any assumptions about agents’ motivations nor assumes that self-interest prevails (Becker 1993).

Mazar et al. (2008) conducted many experiments to put Becker’s model to the test. Participants in their studies were asked to solve as many simple math problems as possible within a few minutes. For each problem they reported solving, they would receive a fixed amount of money (e.g., \$0.50). This payoff, coupled with the fact that the time was not enough to solve all the problems, provided participants an incentive to dishonestly overreport their performance. Participants in one group had their performance

checked by an experimenter – a baseline condition where cheating was not possible. Participants in another group were asked to self-check their performance, pay themselves accordingly, and shred the sheet with the math problems. Hence, not only was cheating possible, but this treatment removed the probability of getting caught and any punishment. In a variation of this experiment, the payoff per problem was four times higher. If people do behave in line with an economic approach, one would expect everyone to cheat possibly to the full extent (e.g., reporting solving all the problems in the set) and proportionally to the payoff. However, the results told a different story. Participants did cheat, but only “a little bit,” just enough to profit from dishonesty without spoiling their idea of being an honest person (Sanitioso et al. 1990).

This result deviates from what a purely selfish agent would do and shows that people care about the psychological cost of lying and prefer to think about themselves as honest (Abeler et al. 2019). This also highlights a fascinating conundrum: How is it possible that people hold two opposing desires at the same time: Reaping the benefits of dishonesty but wanting to feel honest? How do we make the impossible possible?

Justifications: How to Do Wrong but Feel Honest

When people hold two contrasting beliefs (here, being honest but cheating at the same time), they experience a sense of dissonance (Barkan et al. 2015), a tension between doing right or wrong. When it comes to dishonesty, this tension can be resolved by either cheating, or by taking the high road. From a naïve lens, doing both is impossible. However, one process that can make this possible is justifications.

Justifications allow people to interpret facts in a self-serving way. This idea is rooted in the notion of motivated reasoning – people’s ability to arrive at any desirable conclusions as long as they come up with reasonable justifications for these conclusions (Kunda 1990). But how do justifications shape dishonesty? In one experiment,

Shalvi et al. (2011) asked participants to privately roll a die and report the outcome to determine their pay (higher rolls meant higher pay). Some participants rolled only once. Others rolled three times – supposedly to ensure that the die was fair – but only the first roll counted for pay. Reports were higher in the latter condition, where participants frequently reported the highest of the three rolls. Seeing higher (and tempting) rolls made it legitimate for people to excuse their behavior (“I could have rolled a six!”). In the absence of extra rolls, inventing facts does feel quite as legitimate.

Research also showed that people find it easier to justify their behavior if their dishonesty benefits others. Using the same die roll task, Cadsby et al. (2016) found that participants tend to dishonestly overreport higher numbers to benefit ingroup more than outgroup members. Overall, the tendency to tell prosocial lies increases as the number of beneficiaries increases (Gino et al. 2013) and people do not feel particularly guilty about it. The idea that people can be “partners in crime” is also illustrated by Weisel and Shalvi (2015), who found that – even in the absence of communication – people can corrupt others fairly easily, revealing an unexpected dark side of cooperation.

Not only does guilt decrease when people cheat for others vs. themselves, but so does physiological arousal. In a series of experiments, Hochman et al. (2021) found that people who dishonestly benefitted others (vs. themselves only) exhibited lower arousal (measured by a polygraph). In sum, using others to justify dishonesty changes both people’s self-report feelings of guilt as well as their physiological states, the latter of which is outside volitional control.

Although people lie for (and with) others, it is important to note that the magnitude of dishonesty still reflects a general aversion to lying (Abeler et al. 2019). As a case in point, Erat and Gneezy (2012) found that only ~65% of individuals tell a *Pareto* lie (one that increases the welfare of both parties). Thus, using others as a justification for dishonesty reduces, but not eliminates, the threat of spoiling one’s self concept. In sum, this research shows that justifications allow people to make it possible to do wrong but feel moral.

Self-Deception: “It’s not a Lie (If You Believe It)”

There are many situations in daily life where people disregard an often undesirable truth in favor of a more desirable false belief. For instance, even when reality is grim, people can still convince themselves of being better at many things than they actually are (see Alicke et al. 1995). The question is: How it is possible for people to hold a false belief about themselves despite having evidence to the contrary? The answer is self-deception, a notion that ties back to motivated reasoning and people’s desire to see themselves in a positive light. In one experiment, Epley and Whitchurch (2008) invited students to the lab to have their pictures taken. Next, they morphed these pictures to create some more and some less attractive versions of them. Two to four weeks later, the same participants returned to the lab and were asked to pick their original picture among the different versions. It turned out that participants systematically chose a more attractive version of themselves. This did not happen when they had to recognize pictures of strangers, meaning that this “enhancement bias” is self – but not other – serving. But how does self-deception play out when it involves dishonesty?

Chance et al. (2011) had students perform a general knowledge test. Half of them were given the opportunity to cheat by looking at an answer sheet. Half of them were not. Next, all participants predicted their performance on a similar test in the future. Unsurprisingly, participants cheated on the first test when given the answer sheet. But how did cheating affect subsequent predictions? If there is no self-deception, predictions should not differ between groups. However, if there is self-deception, those who cheated should expect a better performance. This was indeed the case. These participants interpreted their dishonesty as a sign of intelligence – instead of disregarding it – and used it to convince themselves of being good test takers. Interestingly, offering monetary rewards for accurate predictions on a second test did not adjust participants’ forecast, suggesting that people might not know that they are lying to

themselves. Ironically, cheaters ended up earning less money.

Similarly, Gneezy et al. (2020) found that participants playing the role of financial advisors were more likely to make recommendations to clients if these recommendations offered advisors a monetary incentive, but only if they knew about the incentives *before* evaluating the investments. These participants were also confident that their recommendation was the one preferred by their clients. In sum, this research shows that self-deception allows people to lie to themselves making it possible to favor a self-serving belief even in the presence of a truthful, yet less desirable one.

Cognitive Biases: The Role of Information Processing

People's perception of reality is malleable, and depends on desires, goals, and motivations – factors that can make people focus on some aspects of what is in front of them while neglecting others (Balcetis and Dunning 2006). At times, these “oversights” are harmless (e.g., visual illusions). However, when it comes to ethical issues, their consequences are much more serious. For instance, after failing to recall the dangerous and deadly Pinto model, Ford managers asked themselves how they could not *see* or *process* the gravity of the problem (Gioia 1992). How was it possible? How could the managers not see all the human loss of bringing the Pinto to market? This section discusses how dishonesty can make it possible to affect low-level psychological factors such as perception and memory. Specifically, it reviews some research showing that temptation and instrumental motives can lead people to *see* and *remember* reality in a self-serving way.

Recently, researchers have begun to trace eye movements to understand the cognitive processes underlying dishonesty. Pittarello et al. (2015) created a computer task that asked participants to report the outcome of a target die roll (among others) indicated by a cue. Reporting higher rolls corresponded to a higher payoff. Sometimes, the die second closest to the cue was higher than the target roll, which made it tempting to report and

allowed participants to make a “self-serving mistake.” Not surprisingly, participants frequently reported the higher rolls, even though it was the dishonest thing to do. Eye tracking analysis showed that these mistakes resulted from more attention allocated to the “tempting rolls” at the expense of correct (but less tempting) ones, a phenomenon labeled “ethical blind spots.”

It remains unclear whether the dishonesty stemming from ethical blind spots is conscious or not. On some occasions, people might deliberately turn a blind eye to their wrongdoings possibly to avoid feeling bad about it. Conversely, on other occasions they might not be aware that their behavior lacks integrity (Jacobsen et al. 2018). For instance, well-intentioned doctors may not be aware of a conflict of interest that leads them to make decisions that favor companies compensating them; they believe they are doing the best for their patients (Feldman and Halali 2019).

Not only does dishonesty affect perception of ethical situations, but also people's memory of them. For instance, Galeotti et al. (2020) found that people engage in “motivated forgetting”: They tend to misremember their past dishonesty if doing so allows them to cheat again in the future. Finally, Pittarello et al. (2022) found that people even tend to remember objects as physically closer to tempting stimuli than to non-tempting stimuli. In sum, this research shows that dishonesty makes it possible for people to literally alter their view of reality via biased information processing.

The “Evil Genius” Effect?

The research reviewed so far highlights the negative repercussions that dishonesty has on individuals. The focus on such a dark side made some scholars wonder: Is it possible that dishonesty promotes any desirable behavior? Clearly, people's morals are flexible and the line between right or wrong is blurred. Flexibility, however, also characterizes another desirable behavior: Creativity. Coming up with novel ideas requires people to find solutions to problems, think “without boundaries” and “outside the box”

(Thompson 2008, p. 226). Building on these commonalities, Gino and Willemuth (2014) tested whether being dishonest can enhance creativity. In one experiment, they asked participants to complete the math problem-cheating task reviewed above. This allowed measuring dishonesty. Finally, the same participants completed a creativity task – finding associations among groups of unrelated words. Unsurprisingly, participants cheated on the math task. Surprisingly though, cheaters outperformed non-cheaters in the word-association task. The same effect emerged when cheating did not yield a monetary incentive but allowed people to avoid a threat to their self-esteem. These results were explained by participants feeling unconstrained by the rules.

It is important to note that the opposite causal path, namely creativity leading to dishonesty, can also be true. Case in point, Gino and Ariely (2012) found that dispositional creativity, but not intelligence, predicted dishonesty. Interestingly, the same pattern emerged when a creative mindset was temporarily primed. However, recent work warns that the relationship between creativity and dishonesty is not so straightforward. For instance, Mai et al. (2015) found that a creative personality leads to cheating only if this personality is activated. Such activation occurs in situations that “provide cues for the expression of trait-relevant behaviors” (p. 77). A recent meta-analysis by Ścigala et al. (2021) found mixed evidence for the link between creativity and unethical behavior. Using multiple objective and subjective measures of creativity, the authors found a negative correlation between *objective* creativity and cheating, and a positive one between *subjective* creativity and cheating. Neither objective nor subjective creativity influenced dishonesty when dishonesty involved deceiving another person. Finally, Keem et al. (2018) suggested that creativity can lead to both honest and dishonest behaviors, depending on the extent to which people value their moral identity. In sum, while only a handful of studies showed that dishonesty can make it possible for people to become more creative, whether creativity makes it possible for people to become dishonest requires further investigation.

The Difficulty of Reducing Dishonesty: What Can Be Done About It?

Alongside theoretical considerations, understanding what drives dishonesty also helps craft interventions that can promote ethical climates. This section will discuss some of these attempts both in the field and in the lab. The underlying question is: Is it possible to make people less dishonest? Or perhaps making the “impossible possible” a less attractive option?

One way to achieve this goal is to leverage on people’s desire to be (and appear) honest. While there are many ways to do so, an intriguing possibility is using subtle cues that remind people about morality. A classic example is displaying a picture of eyes on the wall (see Bateson et al. 2006) with the purpose of making people feel observed (both by themselves and by others, Ayal et al. 2015). Ayal et al. (2019) applied this idea to public transportation fare evasion. They found that displaying eye-cues posters at different train stations was not enough to promote honesty unless these posters were accompanied by messages highlighting how many people obeyed and validated their tickets. The finding is in line with a recent work showing that pictures of eyes alone seem to have small or insignificant effects on honesty (Cai et al. 2015; Northover et al. 2017).

Another less subtle intervention relies on social norms by informing people about what others did in ethical situations. This strategy is often called “moral suasion.” In a series of experiments, Dimant et al. (2020) had participants take part in a cheating task. Before deciding whether to tell the truth or to lie to earn undeserved money, participants were told that the majority of relevant peers *were* honest or thought that one *should* be honest. Surprisingly, neither of these norm messages made people more honest than when no messages were given. This was because they did not change how inappropriate people perceived lying to be. This work also does not tell us whether it is easier to make people more honest or less dishonest. Dimant (2019) had participants complete a series of economic decisions after observing others who behaved prosocially, or antisocially. Overall, participants adjusted their behavior in the

direction of those whom they had observed, indicating social contagion. However, this contagion was asymmetric: Perhaps dishearteningly, the impact of “bad apples” was much stronger than that of “good apples.” Put differently, it is much easier to make people behaving dishonestly than honestly.

Less subtle interventions include moral reminders, frequently operationalized as explicit requests for compliance. Bott et al. (2020) collected data from +15,000 taxpayers in Norway and varied the content of a letter soliciting compliance. One letter contained general information about how to report taxes. One “moral” letter contained information about fairness (e.g., it is important to pay), and another highlighted the societal benefits of paying taxes. A final letter was written in a way that communicated how the authorities had knowledge of the taxpayers’ assets in a bid to elicit fear of detection. Overall, both moral letters and that instilling fear of detection corresponded to greater compliance, but in different ways: Moral letters affected the amount of income reported among those who would have reported less income in the absence of a reminder, whereas detection letters affected the proportion of people who reported any income.

Looking at more “ordinary transgressions,” Pruckner and Sausgruber (2013) studied honesty in the context of paying for newspapers in the street. They varied the reminder attached to a cashbox used to collect payments from customers. A control reminder just reported the price of the newspaper. A legal reminder reported the cost and that stealing a copy was illegal. A moral reminder reported the cost and thanked customers for being honest. The key result was that the moral reminder outperformed the legal, even when such a reminder was subsequently removed.

In sum, this research shows that making people more honest (or less dishonest) is challenging but possible. Because dishonesty spans different unethical behaviors, a “one size fits all intervention” is unlikely to promote large scale changes, especially in the field where many factors cannot be controlled. Furthermore, because these interventions are often deployed at the group level, they fail to consider the heterogeneity of the

population, which might explain why some interventions can even backfire (Pittarello et al. 2021). Finally, it is important to understand people’s acceptance of reminders (or nudges), whether they deem them as ethical, and whether they are seen as paternalistic tools to impose behaviors (see Hagman et al. 2019).

Conclusion

This entry provides a general definition of dishonesty and discusses how we can make “the impossible possible.” Specifically, it shows that justifications allow people to do wrong while feeling honest, how people can lie to themselves (without necessarily being aware of it) and how physiological changes allow people to interpret reality in a self-serving way. Finally, it touches on the controversial topic of whether doing wrong can even promote desirable behaviors such as creativity. It ends by asking perhaps the most important question from an applied perspective: Is it possible to make people more honest (or, less dishonest)? The answer, at least to date, is that it can but that more research is needed to encourage the ethical behavior we all desire across a variety of different situations and heterogeneous population.

Keywords

Divergent thinking · Cognitive hyperspace · Creativity · Originality · IQ · Paradigm shifts · Forecasting

Synopsis

This chapter answers the question of “what is possible” by drawing from theories of creativity. It suggests that creative thinking will provide a wider range of answers to that key question than will logic and convergent thinking. It also points to one particular model of creative thinking, namely, that of divergent thinking, as especially useful. It provides a summary of the research on divergent thinking. This includes the very recent modifications to the model, including those defining cognitive hyperspace. This chapter concludes by putting divergent thinking in the larger context. Divergent thinking is useful but is not synonymous with creative thinking. There are other approaches to creative thinking, though, as noted herein, the divergent thinking approach is

especially useful when considering the question, “what is possible?”

Introduction

The question “what is possible” is enormously important. That is in part due to its breadth: it could be asked within any culture, any era, or any discipline. It no doubt comes to mind any time there is a concern for progress, advance, growth, or evolution. It might be asked by organizations faced with a problem (e.g., how to maintain a competitive advantage) and in need of solutions, or asked by an individual pondering the human condition. How can such a broad question be answered?

The question “what is possible” might be answered via logical inference. Simplifying, such logic might start with the way things are and then logically extrapolate to the way things could be. Current options might be extended or tweaked so they have some new component. The problem with this logical approach is that what is possible may not depend much if any on the way things are, in which case the current situation – and even the current logic – may not predict all possible futures or options. This is precisely what Jerome Bruner pointed to creativity when he thought about the future. He was concerned about the speed of social, cultural, and technological change and argued that because of the speed of change educators must focus on preparing students for a future which is, as he put it, unforeseeable. He described creativity as a way of going “beyond the information given,” which is consistent with the idea above that creativity can provide possibilities that are not apparent from traditional logic. Think also about *paradigm shifts* (Kuhn 1963), which are defined as dramatic breaks in the flow of progress. No wonder Kuhn (1964) pointed to creativity in his theory of paradigm shifts. Indeed, creative processes offer possibilities that may not follow from logical inference.

This chapter explores creative processes and suggests that creative thinking must be used when attempting to answer the question “what is

possible?” It describes a model of creative thinking that is especially fitting when answering the “what is possible?” question.

That model is based in part on the theory of divergent thinking (DT), which is in turn part of a theory called the Structure of the Intellect (Guilford 1968). The Structure of Intellect was proposed decades ago and was antithetical to IQ testing. The IQ approach assumes one general intelligence (“g”), while the Structure of Intellect contains 180 different kinds of cognition. The separation of the 180 “cells” was not supported by data, but one part of that theory held up. This was the distinction between divergent thinking (DT) and convergent thinking. The former describes ideation that moves in different directions, some of which are original and novel, while the latter describes solutions which are conventional and consistent with norms and common knowledge. Divergent thinking is by no means synonymous with creative thinking, but it does provide a reliable method for assessing the potential for creative thinking, and there is evidence that DT is predictive of many creative activities and achievements (summarized by Runco and Acar 2019).

Extensive research has uncovered the value (e.g., predictive validity) of DT but also the limitations. This research is quite useful for the present discussion. The next section of this chapter defines DT, then summarizes evidence tying it to creative potential, and then notes the limitations of the model and methods. Throughout the narrative the usefulness of DT as a way of answering “what is possible” is made explicit.

Divergent Thinking

Divergent thinking is the modern label for what was originally called divergent production and, as noted above, was part of Guilford’s (1968) Structure of Intellect model. Also noted above was that much of that model has been dismissed. This was primarily due to the fact that Guilford used subjective analytic methods for distinguishing the 180 cells. What has endured and held up was the idea of divergence, which has proven quite useful

for understanding and estimating creative potential. Note that tests of DT provide estimates, but this is true of all tests. Tests are samples, and each has some measurement error. If there was no measurement error, test scores would be perfect indicators of creative capacity, but given that there is a modicum of measurement error, they are best viewed as estimates of the target skill or capacity. Along the same lines, it is best to view DT as related to *creative potential*. Just because a person does well on a test does not mean that he or she will actually do well in the natural environment. A person displaying DT does, however, possess what may be the most important part of creative potential, namely, the capacity to produce original ideas.

DT is involved when an individual is faced with an open-ended task. Tests of DT are often simple, and open-ended, and may contain questions like “list alternative uses for a shoe – the more ideas you write down, the better,” or “list uses for a brick.” Other DT tasks are visual rather than verbal, and some ask the person to generate problems rather than solutions. There are also realistic tests which present open-ended situations that a person might actually encounter in the natural environment. Here we have the first aspect of DT that makes it so relevant to the question of “what is possible.” That question is certainly open-ended! And DT reflects a capacity to deal with open-ended tasks.

DT often leads to original ideas, which is why DT tests are so often used when there is a need to estimate creative potential – originality being a prerequisite for creativity (Runco and Jaeger 2012). Originality is apparent when a person uses his or her DT and thereby produces novel or at least rare ideas. Operationally this means that the original person produces ideas that no one else thinks of, or at least very few others. Originality can be scored quite objectively; it is really a matter of statistical infrequency. In fact, new methods for scoring DT tests rely on computers (Dumas and Runco 2018; Hass 2015) and are quite objective. Computers can also be used to score DT for the other two most useful aspects of DT, namely, *flexibility* and *fluency*. The former is calculated from the number of conceptual categories tapped

by the individual when producing ideas and dealing with an open-ended task. The latter is simply the number of ideas produced by the individual. So if the person produces ten ideas when asked to list uses for a shoe, his or her ideational fluency is 10. If those ideas are “for basketball, for cricket, for tennis, for squash, for football, for fashion, to smash bugs, to look tall, protecting feet, to produce bad odors,” flexibility is probably 6 because six conceptual categories are used. The first five ideas there are all in one conceptual category (sports), but the other five are in varied categories. Flexibility is a very important aspect of DT because it is indicative of the individual’s adaptability. A flexible person is unlikely to get stuck in one conceptual category, which means he or she can avoid one of the biggest problems there is when solving problems, namely, getting stuck in one intellectual rut (Adams 1979; Wicker 1985).

DT is best understood by contrasting it with *convergent thinking*. This is used when a problem is closed and can be solved by simply remembering what is the conventional or correct answer. If a task has one correct answer, it will probably only elicit convergent thinking. So while DT leads to numerous ideas, CT leads to one or very few. While DT may be flexible and original, convergent thinking leads to ideas that are conventional and thus unoriginal.

Often, when discussing creativity, DT and convergent thinking are treated like two ends of a dichotomy, but in reality they frequently work together. This is because DT may lead to original ideas, but creativity is more than originality. Creativity also requires effectiveness (Runco and Jaeger 2012). It may sometimes also require authenticity and some aesthetic quality (Kharkhurin 2014), but at a minimum, it requires originality and effectiveness. CT works with originality in actual creativity to insure that ideas are effective as well as original. Detailed explanations for how they may work together have been presented by Eysenck (2003), Cropley (2006), and Runco and Chand (1995).

This view of creative thinking, involving both DT and CT, takes us to another point where we can put into words exactly why creative thinking, and DT in particular, is necessary when answering the

question of “what is possible?” As noted above, answers to that question could be found by logic. Such answers could be found by some linear or associative thinking. True, associative processes can eventually discover a remote associate which is original because it is distant from the initial problem state, but still, linear processes only operate in one or very limited directions. All other things being equal, linear processes are probably best for exhausting one train of thought or for exploring (and perhaps exhausting) one category of ideas or one direction of ideation. That will offer a very limited answer to “what is possible” because the range of things this is possible includes antitheses, opposites, contradictions, and ideas that are only loosely connected to the initial problem space – or not connected at all. DT is useful when the problem space is vague, or changes, or misleading.

To bring this point home, think about an associative chain of thought. As Mednick (1962) described the process there is a starting point (e. g., a problem, question, or just initial idea) and then associations follow. Obvious associates come to mind quickly, before less obvious and common associates. If a person ponders things that howl (the starting point for the process), a quick associate might be wolf, coyote, or dog. This leads to another associate, which leads to another, and so on. There is, then, a chain of associates. Importantly, it is essentially linear and the associations are often found using experience, or traditional logic. After the obvious initial associates, there may be some divergence. Ideas may be found by exploring options and directions that are not connected with traditional logic and perhaps represent very loosely connected branches of thought. That is of course what divergence implies.

Two things should be emphasized: one is that divergence indicates that thinking is moving in different directions. It may also benefit from leaps, where the gap between ideas is large. Barron (1995) referred to this kind of thing as the interstices of thought, and for some people, those gaps might be sizeable. Two ideas may be closely associated (dog:cat, day:night), but they also may be only moderately associated (day:time

or day:sunburn) or even very loosely connected (day:history or day:battery). Thinking may rely on close associates or loose associates, though no doubt most of use both at different times. Very likely certain people are better at using and appreciating loose associates than other people – and are more creative thinkers because of it (Mednick 1962; Acar and Runco 2014).

This approach to creative thinking can be taken several steps further, but we must use our imagination. The extreme view cannot be captured with a two-dimensional graphic. But it can be described: imagine a circle representing all possible ideas, and then one vector, starting from the question of “what is possible” but only moving outward in a linear fashion. This may offer options for “what is possible,” but few if any original or surprising ones. Next consider a sector of that circle – a slice of pie, to use the food metaphor – which offers answers to “what is possible.” The sector is broader, so it is more likely that original possibilities would be found, but still, all ideas are in the same direction and, even more importantly, the same plane. That slice of pie might contain all ideas that are suggested by the current state of affairs or what is currently known and accepted. This slice may offer more than the vector, but still the ideas suggested by what is currently known or accepted do not do justice to everything that is possible. It may not predict paradigm shifts, for example, or things that are possible but not connected to current state knowledge.

To really think about “what is possible,” the entire circle needs to be considered. In fact, it is not a circle; it is a globe, without boundaries. As we shall see, there is a model of DT that helps to describe such wide options to “what is possible.” To its credit, there is some tentative empirical support for this kind of unbounded creative thinking.

Empirical Research on and New Theories of DT

There is empirical support for the relevance of DT for the question of “what is possible,” but before summarizing it, something should be said about

the more general empirical rationale for DT as a useful approach to creative thinking and for DT tests as useful estimates of creative potential. When DT data are collected correctly, the resulting scores are quite reliable and distinct from expressions of general intelligence. What is “correctly”? Simplifying some, DT data should be collected under relaxed or even game-like conditions. What must be avoided are test-like conditions that make an examinee think that there are expectations about correct answers, or that grades or points will be given. DT data collected under this kind of test-like conditions are misleading. There is not much originality. In addition, when DT tests are given under test-like conditions, the scores tend to be correlated with GPA and scores from IQ and other convergent thinking tests. That lack of *discriminant validity* (i.e., the separation of divergent from convergent thinking) is due to the testing conditions. When DT tests are administered as if they are games and conditions are more relaxed, without expectations and evaluations, examinees feel that they can think in original ways and their ideas are independent from convergent thinking. This all applies to everyone, not just selected examinees: individuals who receive DT tasks in test-like conditions may show little originality, but if DT tasks are later given with relaxed instructions, those same individuals are highly original.

The *predictive validity* of DT test scores is also respectable. One investigation used multivariate methods to take ideational fluency, originality, and flexibility into account (as a statistically optimized variate). The canonical predictive validity coefficient was 0.55, which is larger than any predictions using IQ or even personality measures to predict real work achievement. Another study of predictive validity covered 50 years (Runco et al. 2011). The predictive validity coefficient was lower than the 0.55 just mentioned, and predictions were only accurate for certain kinds of real-world creativity, but the prediction was statistically significant (approximately 0.30) – even when the DT data were collected 50 years before the criterion data were collected!

Thus there are reasons to view DT as valuable and scores from DT tests as reliable indicators of

the potential for creative thought. The empirical studies with direct relevance to the “what is possible” question can be summarized next. Several of these use DT tests which contain questions that are directed perhaps not to the future, but to topics that require the same sort of thinking. Torrance (1995), for example, had a test he called *What If*, which was of course open-ended but pointed to things that could possibly occur. The examinee was asked to think divergently about the ramifications of some hypothetical event. Just to name one example, “What if the Earth was covered by water?” Another example of the “What If” task can be found in research on the impact of TV on children’s creativity. This research sometimes shows children an animated show and, after it has ended, asks them “What if this was different?” Of course the “this” was something concrete, such as “What if that character was stronger” or “What if suddenly the witch returned to the village?” This is just one example of how the “What If” task has been used to study creative potential. Interestingly, it seems to be best to ask children “What If?” before a show has concluded. If children have seen the end of some show, they may have trouble thinking of wildly divergent and original alternatives. The ending they saw may constrain their thinking and everything they do think of is similar. This is not far from what was said above about logic: it sometimes leads on one direction and does not branch out to nonlinear directions, and these branches are often where original ideas are found.

Guilford’s (1968) *Consequences Test* is even more popular in the creativity research. It presents examinees with a situation and, like “What If,” asks for ramifications and implications. These two tests contain questions about some unrealistic possibilities (e.g., the earth is completely covered by water, strings hang down from clouds), but that is in part to encourage people to really use their DT. When DT tests are highly realistic, people tend to rely on experience and memory, so they are not as original as they can be (Runco and Acar 2019).

Mumford et al. (1998) focused on what they called *forecasting* – a skill that is by definition focused on future possibilities. Mumford et al.

adapted Merrifield et al.’s (1962) *Consequences Test* for this research. As Mumford et al. (2001, 2002) defined it, forecasting involves the projection of future outcomes. They described how forecasting is a part of (and subsumed under) planning. Mumford et al. go into detail about planning and point to various activities, including backup planning, case retrieval, information gathering, and the refinement of plans. Forecasting is also, for Mumford et al., inherently dynamic and for that reason requires regular monitoring and, very likely, real-time updating. If done correctly, the planning process, which includes forecasting and then updating, is enormously useful to organizations. It allows them to identify contingencies and restrictions in the environment and prevent potential problems before they occur (Mumford et al. 2002). Moreover, an increased range of situations or outcomes can be envisioned through forecasting. Forecasting enables a consideration of a broad range of causes, which may have an impact on outcomes and success. It may point to a direction or even method leading to a preferred outcome.

The “What If?” and *Consequences Tests* were developed some time ago, and although they continue to demonstrate usefulness, as in the work on forecasting, even more telling is the research where the model of DT has itself been modified to allow for thinking that can explore the broadest possible universe of what is possible. This new model may be especially useful for thinking about paradigm shifts and things that are only loosely connected to what is currently known. This model points to *literal divergent thinking* and *cognitive hyperspace*. Those labels sound like jargon but are nicely descriptive and perfectly apt. The first of them, literal DT (LiDT), was proposed when Acar and Runco (2014) reviewed methods used to study DT and found that most constrained the cognitive process such that more linear processes were involved rather than truly divergent processes. They described how tasks used to assess DT or exercise it too often allowed linear thinking or, at most, thinking in a finite number of directions. Imagine the universe of all possibilities depicted as a circle thinking might go in any direction within the 360 degrees implied by the

circle. Most of the time, before the model of LiDT was proposed, DT tests and tasks only considered some small portion of that universe – one constrained segment or sector. That is not full divergence. Far from it. Acar and Runco attempted to expand the measurement of DT to allow for all 360 degrees. They labeled the processes used for such broad ideation literal DT.

In fact they described creative thinking that can go beyond 360 degrees, which is where cognitive hyperspace comes in. This concept was suggested by the fact that a circle is two-dimensional, and this implies that thinking does not literally go in all possible directions. A circle allows 360 thinking, but Acar and Runco argued that individuals can go beyond linear thinking and go beyond two-dimensional thinking. Individuals can find additional alternatives by exploring perpendicular, multidimensional paths of thought.

Think of it this way: there may be one associative chain of thought which follows one linear logic. If the conditions are right, that line of thought can take a right turn and explore very different ideas – ideas that would not be found if only linear thinking was used. It is a right turn in the sense of being perpendicular, and it is perpendicular in the sense that the ideas found are extremely different from those found along the original line of thought. Ideas in the original line of thought may all relate to technology, just to name one conceptual direction, but then there is the turn, and the ideas now relate to food, or economic, or something quite different.

Keep in mind that the physical world only allows three dimensions, but the cognitive world is not so constrained, and in fact a person can make another right turn and explore another perpendicular line of thought, and another, and another, and another, into cognitive hyperspace. This is not random thinking if the person is following a process, and there is one connecting point or intersection for each perpendicular. Thus instead of a 2D circle representing the universe of what is possible, the theory of LiDT and cognitive hyperspace imply that there is some n -dimensional realm that more accurately depicts “what is possible.”

Note that this allows much more originality than “out of the box” thinking. Out of the box thinking might very well be two-dimensional. It is better than in the box thinking, but not as rich as explorations of cognitive hyperspace.

This approach to DT and the theory of LiDT is quite relevant to the focus here and the question of “what is possible,” but first it may make more sense if the actual tasks used in the research are briefly described, even though they are in their infancy. The most relevant aspect of the method used for LiDT is that which examines ideas that are feasible and ideas that are not feasible. Various other dimensions of ideation can be (and have been) examined; and in fact feasibility is not the end-all for addressing the question of “what is possible?” What is not feasible now may be feasible in the future. Just look at airplanes, or cellphones, or walking on the moon. Not long ago those were each considered infeasible.

Acar and Runco (2015) examined LiDT with fairly traditional tests of DT. The innovation was to develop a scoring system that captured cognitive hyperspace. Of course not every direction of thought could be operationalized! This was the first attempt at LiDT so it was only vital to go beyond two or three dimensions. Acar and Runco did review previous research on DT and were able to identify 13 dimensions of thought that could be used to categorize all ideas from a set of 6 tests of DT. Initial analyses showed that 11 of the 13 dimensions were highly reliable so subsequent analyses focused on these 11 categories. Importantly, each category was dichotomous so the dimensionality of the scoring was much more complex and closer to cognitive hyperspace than 11 dimensions may sound. Analyses indicated a dimensionality of thought (where an individual’s ideas did in fact represent nonlinear thinking) was correlated with other measures of creative potential, including originality. This was true even with ideational fluency (the number of ideas produced) statistically controlled. The key dimensions were impractical, synthetic, breadth, non-natural, infeasible, playful, and remote – all at the same time. Several

dimensions, including practicality, were negatively related to originality. Acar and Runco did calculate an overall index of LiDT from all dimensions, which was also correlated with an index of originality, even after fluency was statistically controlled. They concluded that LiDT can be empirically examined and that future research might expand on the number of dimensions used when scoring DT. Even with the initial 11 dichotomous dimensions, it is easy to see how looking to LiDT would offer a wide range of options when considering the question, “what is possible?”

Conclusions

Much of the research cited herein used test of divergent thinking. This should not be taken to imply that divergent thinking is synonymous with creativity. There are other theories of creative thinking. The emphasis here on divergent thinking reflects the fact that the theory is compelling and the measures are reliable, and they are especially helpful when thinking about possibilities and optional solutions, including those that could be used to answer the key question, “what is possible?” If the intent is to understand creative thinking as it might be used in other ways, in addition to the key question of the present volume, then things that work with DT should be recognized. Runco and Chand (1995) put DT into a larger framework and presented a process model of creative thinking that included, first, problem finding and then moved to DT (where options are generated) and then to evaluation and judgment (where ideas are selected and tested). They also included extracognitive influences on this process because DT is influenced by knowledge (both declarative and procedural) and motivation (both intrinsic and extrinsic). Guilford (1968) and others have also pointed to influences on DT and processes that may work with it. The point is that DT does not work in isolation.

Along the same lines, the very first paragraph of this chapter might be revised because it is simplistic to completely eliminate logic when thinking about DT. As a matter of fact, Runco

(2006) described a logic (or systematic processing of information and drawing of inferences) that may be unique to and required by creativity. The idea here was that DT and other forms of creative thinking are consistent, even though they lead to original insights – insights which may not be obvious when using traditional logic. Simplifying some, the logic that is unique to creativity may include or “weigh” original elements and details heavily, given that creative insights must be original. There may be a logic to creative thinking, but it may not appear to be logic because it differs from traditional logic.

This volume contains numerous chapters, each of which says something about “what is possible.” One of the other chapters focuses on *malevolent creativity*. There is an interesting and important overlap between that chapter and this one. This overlap results from the fact that when DT or LiDT is used, thinking may go in all kinds of directions, and unless there is some guidance or constraint, some of these might be socially desirable, but others might not. DT can lead to both benevolence and malevolence. If there are few or no constraints on the DT, both are likely, and perhaps equally likely. Malevolence is not really a desirable thing, and it may be tempting to direct DT so that only benevolent ideas are generated. Yet that kind of constraint will not just preclude malevolence. It will also cut down on the overall number of original and benevolent ideas. Thus this is not just a theoretical concern. Teachers and managers who wish for very original ideas must be prepared for all kinds of ideas – ideas from every direction, not just the directions that are consistent with their own values and expectations.

Some theories of creativity do not recognize divergent thinking at all. Quite a few point to combinatorial processes. These describe how a seemingly new idea may arise from the recombination and rearrangement of existing ideas (or bits of information). The interesting thing about this approach is the implication that there is no actual originality. After all, if a seemingly new idea is simply the recombination of what already existed, the new idea is really not entirely new. The pros and cons of theories that point to DT or combinatorial processes are explored elsewhere,

and for the present purposes, what is most important is that the recombination approach to creativity may not lead to a very wide range of options when answering the question of “what is possible?” It would probably not lead to as many options as DT, and the theory of LiDT leads to even more options than the original DT model. These two approaches, describing DT or LiDT, describe thinking that leads to a very broad range of options, some of which may in turn lead to original answers to the question of “what is possible.”

boundaries

Definition

Dante's *Divine Comedy* is fully engaged with the possible, for the poem is the imagining and setting into words of a completely realized possible world. This possible world – or virtual reality – is designed in such a way as to compel readerly suspension of disbelief. The diffusion of the text in the first decades of the fourteenth century prompted the arrival of two support industries, one providing commentary on the text in prose and the other providing illustration in images. These industries, which have flourished from the fourteenth century to our own times and are now global in nature, are the standard responses to the creation of a possible world, as the case of Tolkien demonstrates. But Dante's imagining of the possible does not stop at the creation of a text that has a legitimate claim to be called our premier virtual reality. He conjures a paradise that is a true going beyond space-time and, indeed, an anticipation of modern physics. In this way, and also in social-cultural ways, Dante imagines a possible that stretches the mental boundaries of the world he lived in, and that in some ways still challenges us today. He transgressed the boundaries of his world socially: for instance, Dante imagines the possibility of saving outcast groups, such as virtuous non-Christians and homosexuals. He also imagines that women need not be silent, as per the Pauline dictum, but can be great teachers, although young and beautiful. Dante gave posterity the gift of the possible.

The Possible *Divine Comedy*

The *Divine Comedy*, a long narrative poem of 100 cantos written in Italian in the first decades of the fourteenth century by Dante Alighieri (1265–1321), tells the story of the author's journey through the Christian afterlife. The Christian afterlife as it was conceived in pre-Reformation Catholic Europe comprised hell, purgatory (as a relatively recent addition, purgatory would be excised by Protestants; see Le Goff), and paradise. Dante's poem therefore comprises three volumes: *Inferno*, *Purgatorio*, and *Paradiso*. According to Dante's fiction, the journey took place in the year 1300, when the poet was “in the middle of the path of our life” (*Inf.* 1.1); Dante was, conveniently, 35 years old in 1300. The chronology of the fiction is minutely sustained throughout the work by complex astrological indications of the time of year (at the beginning of the journey it is spring-time, in the sign of Ares) and time of day, and the fiction itself is buttressed by elaborate truth claims that insist on the revealed nature of the journey and of what the poet witnessed.

The acceptance of the fictional nature of the *Divine Comedy* has been hard won, in critical terms. Authors who create fully realized possible worlds, compellingly realistic virtual realities, have various methods of bringing about the suspension of disbelief in their readers. That suspension of disbelief and what it allows the reader to experience is the great gift of art; indeed, it is the gift of the possible. But it also clouds critical response, and never more so than in the case of Dante's poem, which is a virtual reality based on a revealed religion. A virtual reality that is based on a revealed religion poses a much more complex critical problem than most fantasy fiction, given that in such a case the response to the work of art – the suspension of disbelief that it provokes – is conflated in the minds of many readers with belief in their religion. Because of the religious nature of the content of Dante's poem, the commentary tradition, which originated in Italy in the fourteenth century, frequently gives the impression of accepting the truth claims of the poet, while caviling over this or that rhetorical choice or

emphasis. Twentieth-century critics like Auerbach, Singleton, Nardi, and Barolini have striven to disentangle the poem written by Dante Alighieri from the religious presuppositions that support it. But Dante is a wily poet, and the *Divine Comedy* is remarkably capable of generating suspension of disbelief even among secular readers.

The ability of the *Divine Comedy* to provoke readerly suspension of disbelief is commensurate with its ability to create a possible world so compellingly real that we can legitimately consider it our premier textual virtual reality. The “proof” of such status is that the diffusion of the text immediately spawned two industries that began in the fourteenth century and continue to flourish today: one provides commentary to the text in prose and the other provides illustration in images. Both industries indicate that readers were responding to a perceived “reality” that required glossing, scholastically and figuratively. The scholastic tradition of accompanying commentary glosses the text and thereby aids the reader in reconstructing the possible world that Dante constructed; it began in the fourteenth century in Italian and Latin, and is now a global industry. Painters too responded immediately and a vast treasure house of illustrations of the *Divine Comedy* now exists, in a tradition that began as illuminated manuscripts and that now spans many media and many nationalities.

Narratological analysis has illuminated the kinds of techniques that Dante used to create his possible world (Barolini 1992). These techniques span the gamut from the flashy and overt to the micro and unnoticed. Dante’s explicit claims of being a truth-teller include his addresses to the reader (Auerbach 1954; Spitzer 1955). Dante frequently claims the status of inspired truth-teller, whose inspiration derives directly from a transcendent source, as in the invocation to Apollo at the beginning of *Paradiso*. We can see here not only Dante’s habitual conflation of classical divinities with the Christian God but also his understanding of inspiration as a literal “breathing into”:

O good Apollo, for this final task
make me the vessel of your excellence,
what you, to merit your loved laurel, ask.

Until this point, one of Parnassus’ peaks
sufficed for me; but now I face the test,
the agon that is left; I need both crests.
Enter into my breast; within me breathe
the very power you made manifest
when you drew Marsyas out from his limbs’
sheath. (*Par.* 1.13–21).

Dante is also supremely clever at embedding into his text quasi-subliminal truth claims that are not noticed as such (Barolini 1992). Techniques of this sort belong to a kind of representational mirror game that is on display in the opening verses of *Inferno* 3, where we encounter words that are allegedly written by the gate of hell itself, rather than by the author of the poem. The famous beginning of *Inferno* 3 – “Through me the way into the suffering city, / through me the way to the eternal pain, / through me the way that runs among the lost” – are composed in a first person singular that is usually not interrogated by commentaries. The “I” of hell’s portal presents itself as confidently and unquestioningly, and as mendaciously, as the “I” on the computer screen of a bank’s automatic teller that announces, “Sorry, I am temporarily out of service.” A measure of Dante’s success in using such tactics is provided by the history of critical response to these verses, which has rarely stopped to consider how they invest the subjective author of the *Inferno* with the objective authority of the divine “author”: the divine maker of hell.

In this way, Dante works to blur our sense of the distinction between the fabricated text and the allegedly nonfabricated reality of which it tells. Other such embedded truth claims are even less noticeable. For instance, remaining in *Inferno*, there is Francesca’s claim that the husband who murdered her is now in “Caina” (*Inf.* 5.107). A reader has no way of understanding this statement without the help of a commentary (this is an excellent example of why commentaries were immediately required). Dante has his character supply a topographical name, without explanation that “Caina” is the (invented) name of the circle of traitors in his (invented) hell. Dante thus works, subliminally, to convince us that the names of his virtual reality are “real”: the implication of Francesca’s statement is that *Caina* is a real place whose whereabouts are known and do not

need to be glossed. A similar subliminal truth claim involving location is the verse that opens *Inferno* 18: “There is a place in Hell called Malebolge.” Again, Dante confers truth status on the place in his hell that he names “Malebolge” (Evil Pouches) by implying that it is so named by others: by whom, after all, is this place “called” Malebolge? These are all examples of the same kind of representational illusionism that is inaugurated by the writing on hell’s gate.

Embedded truth claims indicate a reality that exists outside of our frame of reference and thus confer reality on the possible world being created. Dante also explicitly tells his readers of a reality beyond our frame of reference. For instance, the opening verses of *Inferno* 21 declare: “We came along from one bridge to another, / talking of things my Comedy is not / concerned to sing.” What are those things of which Dante and Virgilio were speaking as they made their way over the bridges that connect one evil pouch of Malebolge to another? If only we knew. . . Similarly, Dante peoples his afterlife with some fictional characters but mostly with historical persons who lived before us: whether this be a dynastic wife like Francesca of Rimini (*Inferno* 5) or the great Roman poet Vergil, the first character whom Dante meets (*Inferno* 1). Techniques of this kind function as remarkably effective contributors to a textual metaphysics that seeks to persuade us to accord it the status of reality. The reception of the *Divine Comedy*, which reveals the degree to which critics as well as readers have historically participated in an uncritical and almost unconscious belief in the poem’s truth, indicates that Dante’s quest to be taken as truth-teller has been spectacularly successful.

Dante’s creation of a fully realized virtual reality also encompasses a carefully thought-out topography and mythography for his afterworld. In *Inferno* 34, he explains the creation of hell and Mount Purgatory (Dante was the first to imagine purgatory as a mountain) as the result of Lucifer’s fall from heaven. In falling from his position as the highest of the seraphim, Lucifer excavated the cone that became hell; the displaced earth became Mount Purgatory. In his journey through paradise, in particular, Dante embraces metaphysical ideas

that in his culture were categorized as forms of mysticism and ecstasy, but that he was unusually able to think through and configure physically and geometrically. There are ways, indeed, in which *Paradiso* anticipates modern physics. This is the thesis put forward by Mark A. Peterson, in his essay “Dante and the 3-sphere,” abstracted as follows: “We describe three different methods of visualizing the ‘closed universe’ S^3 , and point out language in Dante’s *Divine Comedy* which suggests that he visualized his universe in the same ways, making his universe topologically S^3 ” (Peterson 1979, p. 1031). Dante conjures a cosmology that builds a paradise that is not the traditional pastoral garden or heavenly Jerusalem, but that instead allows for a true going beyond space-time. As a philosopher, Dante offers his readers an investigation that anticipates the ideas of modern physics; as a writer, he anticipates the idea of time-travel.

A constructed possible world of such precision, one that is also a work of art of extraordinary caliber, cannot avoid being a vast thought experiment: a vast clearinghouse of the possible. This aspect of the *Divine Comedy* has been occluded by its success: to the degree that the poem has traditionally been accepted as a true (enough) description of the Christian afterlife, one that is frequently cited in Catholic Encyclopedias with no acknowledgment of its heterodoxy, its many ideological deviations and inventions have been ignored or even suppressed. There have been cultural forces at work in abetting such suppression, which we can see even in recent times, for instance, in the inaccurate invocation of Dante in the debate on same-sex marriage in Italy. Dante’s deviations from orthodoxy and from cultural norms constitute an investigation into the possible, one that has special value because of the cultural status of the *Divine Comedy*: its relationship to received religion and therefore to human belief.

For instance, in the area of gender and sexuality, an area that has traditionally been severely policed by cultural norms, Dante is an outlier. While he puts male “sodomites” in his hell, he also puts unidentified sodomites on the terrace of lust in his purgatory, a fact that has been far less

noticed over the last seven centuries. Given that all souls in purgatory are saved, and are perfecting themselves in preparation for their transfer to paradise, by placing sodomites in purgatory Dante effectively creates the category of saved sodomites. Dante puts a group of homosexuals next to a group of heterosexuals on the terrace of lust in purgatory (*Purgatorio* 26), where both groups purge their excess lust. In Dante's possible world, the status of the two groups of souls on purgatory's terrace of lust is identical and equal: both homosexuals and heterosexuals are equally saved and equally destined for residence among the blessed in paradise.

The presence of same-sex lustful in purgatory was brought to the fore in Dante criticism only quite recently (Boswell 1994; Pequigney 1991), indicating that Dante's thought experiment of saved homosexuals had been rejected or at least ignored by many of his readers. In fact, truth be told, Dante's cultural authority has traditionally been used to counter and to quench the possible. Thus, Dante's authority was deployed in a debate on the possibility of same-sex marriage in Italy by a former Italian Prime Minister, who noted that "i sodomiti nella *Divina Commedia* finiscono nell'inferno" [sodomites in the *Divine Comedy* end up in hell] (Calabrò 2007). Dante does put sodomites in hell, but he also puts them in purgatory, and therein lies all the difference.

With respect to women, too, Dante sees possibilities not envisioned by his culture. His *exposé* of the political ills of his society focuses on the ways in which the consolidation of power in the hands of "tyrants" corrupts society, enabling greed and denying freedom. The same analysis also demonstrates how the power dynamics in dynastic families corrupt the bonds of familial love and affection: wives and children are passive pawns to be deployed by the powerful in the great game of dynastic politics. This analysis is the backstory of Francesca da Polenta of Ravenna, damned in the circle of lust in *Inferno* 5. Her arranged marriage to Gianciotto Malatesta of Rimini, in pursuance of an alliance between their fathers, the lords of Ravenna and Rimini, resulted in Francesca's love affair with Gianciotto's brother Paolo and their deaths at the hands of the

enraged husband. Francesca was unimportant, in dynastic terms; her murder circa 1286 had no effect on the continuing alliance between the families, which was pursued by her brother after her father. Her life and death were destined for historical oblivion. Francesca's name appears only in the 1311 will of her father-in-law, and only because he discusses her dowry. Had it not been for Dante's account in the *Divine Comedy*, Francesca's name would have been lost to history (Barolini 2000).

Dante shows that he is able to imagine the desperation of the dynastic wife and to give her a voice and a name. This is what he does in *Inferno* 5, making of the unknown Francesca a cultural touchstone and icon, the heroine of countless retellings in many media. Dante's interest in the victimization of dynastic women continues with the brief account of Pia de' Tolomei (*Purgatorio* 5), who was murdered by her husband, and then with the stories of Piccarda Donati and the Empress Constance (*Paradiso* 3): both were forcibly removed from convents to which they had gone voluntarily, and constrained into dynastic marriages against their will. Piccarda was Florentine and sister of Dante's good friend Forese Donati, so her story was well known to him. All these narratives accord personhood to women who were denied agency while they lived. In this way, Dante insists on the issue of female agency, female volition, and makes the case that will and agency are features of all humans, not only of men.

The most famous woman of the *Divine Comedy* is Dante's early love and guide, the Florentine Beatrice Portinari (her last name comes from Boccaccio, not from Dante's own writings). To understand the transgressive nature of Dante's Beatrice, it is important to consider the point made by Joan Ferrante, who explains that Dante puts her "in a role which is specifically forbidden to women by major theologians, as priest, as confessor and teacher of theology" (Ferrante 1992, p. 4). Labeled by one critic *Beatrix loquax* or "loquacious Beatrice" (Barolini 1992, 2006), the amount and variety of speech afforded to Beatrice in the last canti of *Purgatorio* and *Paradiso* is remarkable. Beatrice's voice is not gender-specific; she

speaks with male authority, as teacher, philosopher, and indeed theologian. Ferrante (1992) points out that Dante's Beatrice behaves "in flagrant defiance of Paul's injunction, frequently echoed in the thirteenth century, against women teaching" (p. 4). While there is a tradition of female abstractions who speak authoritatively, like Lady Philosophy in Boethius's *Consolation of Philosophy*, there is no precedent for such verbal authority coming from the mouth of a historical woman: a young woman, a woman described as beautiful and desirable. Beatrice's voice is the amplified and commanding version of the voices of other women like Francesca, Pia, and Piccarda. Most of all, Beatrice's voice testifies to the possible: a possible that was beyond the ken of Dante's early readers, and that still challenges us today.

Another arena in which Dante gave his readers the gift of the possible is with respect to the cultural other, a topic that requires a brief discourse on the idea of Limbo. In the Catholic imaginary, Limbo is a place in hell where the pain of hell is mitigated for some souls, souls whose special status confers upon them a special exemption. Because of these extraordinary privileges, Limbo was defined by theologians with care and precision. Limbo consisted of a *limbus patrum* ("Limbo of the fathers"), the temporary condition of Old Testament saints as they awaited their liberation by Christ, and a *limbus infantum* or *limbus puerorum* ("Limbo of infants" or "Limbo of children"), the permanent condition of infants and children who died prior to baptism. The Old Testament saints were liberated by Christ when, immediately following the crucifixion, he entered hell and transported the biblical righteous to paradise. Therefore, after the death and resurrection of Christ, there were no more adults in an orthodox Limbo. There were only unbaptized children.

Dante's Limbo, in *Inferno* 4, is unlike any other in the history of this religious idea (Barolini 2022). For, after noting the presence of infants in one word, Dante's attention is given over to the other group with which he populates his Limbo: adult virtuous non-Christians.

Dante's Limbo houses mainly pagans who lived virtuous lives before the advent of Christianity, and whose only sin was lack of baptism.

Along with the many Greeks and Romans of classical antiquity whom Dante places in his Limbo, he also includes three virtuous Muslims, born many centuries after Christian baptism had become available. The deviation from orthodoxy here cannot be overstated: in 1300, when, Dante took his journey to hell and arrived in Limbo, an orthodox Limbo could contain only unbaptized infants and children. And yet, Dante imagines that his Limbo, which by the way is also the only part of his hell where there are amenities (light, a noble castle, a lovely green meadow, and a charming little river), can be made available not only to the unbaptized children of Christian parents but to virtuous non-Christians. What accounts for so startling a deviation, so noteworthy a transgression?

The answer is an obsession with justice. Nor is this obsession a fluke, expressed in *Inferno* 4 and then forgotten. In *Paradiso* 19, Dante again raises the question of virtuous non-Christians, pointedly challenging the divine justice that could condemn a perfectly virtuous man, one who is virtuous in all his actions, simply because he happens to be born on the banks of the Indus river, where there was no one to inform him of Christ's existence:

A man is born along
the shoreline of the Indus River; none
is there to speak or teach or write of Christ.
And he, as far as human reason sees,
in all he seeks and all he does is good:
there is no sin within his life or speech.
And that man dies unbaptized, without faith.
Where is this justice then that would
condemn him?
Where is his sin if he does not believe? (*Par.*
19.70–78)

The fixation with justice that fuels the outrage in the above verses also focuses on the issue of equity of access. Thus, the poet formulates his challenge in terms of the modalities of cultural transmission: the man born on the banks of the Indus lives where there is no one to speak or read or write of Christ. How then can it be just to punish him?

The challenge to orthodoxy that rings out in the questions of *Paradiso* 19 – "Where is this justice that would condemn him? / Where is his sin if he does not believe?" – is also the spirit that animates

Dante's Limbo. In *Inferno* 4, Dante gives himself the gift of the possible: he imagines that the great accomplishments of classical philosophers, writers, statesmen, and warriors are such as to merit an eternity of conversation in the noble castle and pleasant green meadow that constitute his Limbo, the first circle of his hell. And that three virtuous Muslims partake of the same special dispensation. The names of these noble souls resound throughout *Inferno* 4: 15 Greeks (Homer, Aristotle, Socrates, Plato, Democritus, Diogenes, Anaxagoras, Thales, Empedocles, Heraclitus, Zeno, Dioscorides, Euclid, Hippocrates, and Galen), 15 Romans (Vergil, Horace, Ovid, Lucan, Aeneas, Caesar, Latinus, Lavinia, Brutus, Lucretia, Julia, Marcia, Cornelia, Cicero, and Seneca), and 3 Muslims (Avicenna, Averroes, and Saladin).

And then Dante goes even further in giving himself license to imagine the possible and imagines that his possible world features also saved virtuous non-Christians.

We encounter the first saved pagan in *Purgatorio* 1: Cato of Utica, the Roman statesman for whom Dante had already expressed great reverence in his philosophical treatise *Convivio*. Later in *Purgatorio*, Dante will add the Roman poet Statius to his roster of saved pagans; finally, in *Paradiso*, he will add also the Emperor Trajan and Ripheus the Trojan. It is important to remember that the total exclusion of pagans from paradise would not have been problematic for Dante's original readers. As Kenelm Foster pointed out: "Catholic theology by and large did not much concern itself with the ultimate destiny, in God's sight, of the pagan world whether before or since the coming of Christ"; moreover, the "concept itself of *fides implicita* was not lacking . . . but it was hardly a central preoccupation of theologians, nor, in particular, do its implications for an assessment of the spiritual state of the world outside Christendom seem to have been taken very seriously" (Foster 1977, pp. 171–72).

It is also worth noting that Dante does not include contemporary Jews (as distinguished from biblical Hebrews) anywhere in his hell. This can be considered a fault (Tomasch 1998), given especially that Dante goes so far as to

include three Muslims among the virtuous non-Christians in Limbo. But one can also argue, especially in light of considerable medieval visual evidence that shows Jews in hell, that the avoidance of Jews in Dante's hell is a positive feature. In a context in which visual representations of hell were full of contemporary Jews, depicted with the stereotypical markers that served to identify them (Strickland 2003), the absence of any contemporary Jews in Dante's hell may be a good thing. In particular, it seems very noteworthy that Dante does not include Jews among his usurers in *Inferno* 17, although usury was a sin commonly imputed to Jews in the Middle Ages. Dante seems rather to go out of his way to make his usurers Christians from famous Italian families, and even to put around their Christian necks the moneybags that contemporary iconography typically associated with Jews (Barolini 2011 and 2022).

Why is Dante given so little credit for the openness that we find in his work? Dante's radical thought has been absorbed, defused, and ultimately effaced by the centuries of normalizing effected in the cultural sphere by the mechanisms of acculturation deployed by both the Church and the nascent Italian State. Of course, Dante is unusual only in the degree to which this destiny of acculturation awaited his masterpiece. The destiny of all successful and compelling radical thought is to be absorbed, defused, and ultimately effaced by Time: the destiny of truly immense cultural statements that meet with societal approval is to come to seem natural. Students respond to Dante's choice of the Roman poet Vergil to be his guide as obvious, natural, and discounted, when in fact, in Dante's time, it was anything but discounted: it was an unusual choice, an avant-garde choice. Because of the movement we call humanism, a movement that Dante's choice of Vergil as his guide heralded, his decision has come to seem obvious. Similarly, readers do not respond with amazement to Dante's claim in *Inferno* 11 that the structure of his hell derives from Aristotle's *Nicomachean Ethics*: time has drained all shock value from the spectacle of a Christian author claiming a pagan philosopher as his authority on sin.

Ironically, therefore, great cultural success results in radical thought that becomes invisible, either because it has been accepted and absorbed or because uncomfortable ideology in culturally sanctioned canonical texts tends to be reconfigured or ignored. The reception of the *Commedia* resulted in both kinds of invisibility: the selection of a classical pagan guide through the afterlife and of a classical pagan template for hell has been accepted to the point of no longer manifesting the deep commitment to humanism that it revealed in Dante's time; conversely, Dante's progressive treatment of sodomy was for centuries ignored by the commentary tradition and effectively elided from the poem. In the areas where the culture at large was not prepared to sanction or truly wrestle with Dante's vision, areas that include his most important and original ideological choices (for instance, that of a young female avatar of the divine), his choices are papered over or reconfigured, generally through allegory.

As a Christian, Dante believed in free will and was against the deterministic view, which he labels "Platonic" in *Paradiso* 4, that souls return to their natal stars. One could argue that an openness to the possible is technically the default position to anyone who is strongly committed to belief in free will. But such an argument is not convincing, for there are many Christian thinkers who are anti-deterministic but are not remotely as open to the possible in the social or cultural domains as Dante was. He seems to have seen ahead, to have been open to possibilities for humans that the society he lived in did not see or value. The *Divine Comedy* certainly seeks to impart moral lessons with respect to the vices to avoid and the virtues to attain if one wants to achieve salvation in the afterlife. But Dante also left his readers remarkable lessons with respect to what humans can hope to achieve in this life. Quite the contrary to the received opinion that holds Dante a teacher of Catholic dogma, rigid and monolithic, Dante is a radical thinker who shapes his possible world to interrogate the universe with respect to justice, freedom, equity, free will, and agency. He gave the gift of the possible.

Dreams

Neil German
Webster University, Geneva, Switzerland

Abstract

Dreams have long connected mankind to an unknown dimension and fascinated human beings for thousands of years, thus inspiring them to realize a potential within themselves and to delve into the mysteries of what must have seemed an incomprehensible world. References to dreams can be found in ancient civilization such as Mesopotamia, Egypt, Greece, and Rome; however, it is easy to imagine that dreams inspired humanity way before and guided the great strides in human development such as the discovery of fire, the hominids migration out of Africa, and the cave art found throughout Europe.

Although the outlook on dreams has changed towards history, the common thread from the ancient civilizations to our modern times is the impression that dreams connect us with another world which can generally be identified with a beyond that transcends human contingences and yet is concerned with them. Be they messages from the gods, from the dead, or from the unconscious, dreams intervene to support and guide human life with a symbolic language that needs interpretation. The attempt to understand the oneiric language is another thread that runs throughout the history of dreams and points to the need for humans to search for meaning.

This entry presents a short history of dreams, which highlights the human relationship to the beyond, from the ancient

civilizations to the more recent psychodynamic approaches in psychology, with particular attention to Freud and Jung. It also shows how dreams express and foster the possible in many ways: Through their symbolic and multilayered language and through their connection to the unconscious, they inspire creativity in artists and in daily life, influence scientific discoveries, and culture.

Archetypes · Dreams · Dream history · Individuation process · Music · Possibilities · Repression · Science

Dreams connected the earthly human experience to the world of the beyond, since they were messages from the gods whose purpose was to warn and guide human life. They were similar to an oracle in that their language was symbolic and needed interpretation. With the advent of writing, we have evidence of civilizations' fascination with dreams. The Mesopotamians, Egyptians, Greeks, and Romans had extensive and similar views on the origin and purpose of dreams, which were centered on religion, gods, and divination.

Ancient civilizations considered dreams as messages from the beyond, that is, the realm of the gods and the dead, that needed to be understood and integrated into daily life. Dreams guided important decisions both in private and public sphere, such as where to construct a building or whether or not to fight a war; they supported physicians in their work with the sick; they forecasted the future and represented a transitional space where humans could interact with the deceased and the supernatural. However, the messages from the beyond came in a symbolic language that could not be understood by many and needed interpretation. The "interpreters" were those who had wisdom and held a closer connection with the supernatural. They played an important social role and often had a lot of power.

Both in Mesopotamia and in Ancient Egypt, priests had the role of regulating the relationship between gods and humans, which granted them a

high social position and made them second only to the king or the pharaoh. Although they were mainly in charge of rituals, some of them had the gift to read the propitious signs in order to maintain the gods happy. Among the signs were omens and dreams.

Sometimes, dreams were interpreted literally; other times, great thought and contemplation was needed to understand the message from the other side. Skilled understanding of a prognostic dream had great implications for the society at large, but also for the interpreter. An example of this is the dream of the Pharaoh from the bible and how Joseph interpreted it, which was beneficial both to Egyptian society and to Joseph himself.

After two whole years, Pharaoh dreamed that he was standing by the Nile, and behold, there came up out of the Nile seven cows, attractive and plump, and they fed in the reed grass. And behold, seven other cows, ugly and thin, came up out of the Nile after them, and stood by the other cows on the bank of the Nile. And the ugly, thin cows ate up the seven attractive, plump cows. And Pharaoh awoke. And he fell asleep and dreamed a second time. And behold, seven ears of grain, plump and good, were growing on one stalk. And behold, after them sprouted seven ears, thin and blighted by the east wind. And the thin ears swallowed up the seven plump, full ears. And Pharaoh awoke, and behold, it was a dream. So, in the morning his spirit was troubled, and he sent and called for all the magicians of Egypt and all its wise men. Pharaoh told them his dreams, but there was none who could interpret them to Pharaoh (Genesis, 41, Verses 1–8).

Joseph, who was a Jewish slave and had been in jail, was known for his capacity to understand the language of dreams. In spite of his humble origins, he was summoned to interpret the Pharaoh's dream, which he did successfully in recommending to save as much food as possible for 7 years to prepare for the following 7 years of famine. This brought him good fortune because he was elevated to the Viceroy of Egypt.

The Greeks continued the Egyptian tradition of considering dreams as messages coming from the gods and a way to predict the future. Dreams could guide human actions, warn against dangers,

and inspire creativity. They also offered a glimpse into the mystery of the unknown and soon became a source of inspiration in literary creation (Del Corno 1982).

Dreams permeated ancient Greek literature from Homer to Plato and were integrated in the broader narrative. In the *Iliad*, gods support this or that party and used dreams to influence human actions. The second book opens with a dream that Zeus sends to Agamemnon, in the person of Nestor, to convince him to immediately attack Troy with the deceiving message that, in so doing, the Achaeans would have an easy victory.

In the book 19 of the *Odyssey*, Penelope asks Ulysses, whom she believed to be a beggar, to interpret a dream of hers where an eagle came down and killed the 20 geese that were around her. Ulysses took the dream as prognostic of her suitors' defeat. Another example of prognostic dream is Socrates' dream 3 days before he was put to death: "A beautiful woman in white robes came to him quoting the *Iliad*, To the pleasant land of Pythia on the third day thou shalt come" (Kramer 1988, p. 193).

The Romans were people of action who gave much importance to divination and had several methods of predicting outcomes. Haruspicy, the reading of animal intestines, was one way of understanding the future along with *auspiciu*m, the reading of the flight of the birds. These practices stress the importance of reading the signs before acting, in order to understand whether the gods gave their approval. In this context, dreams were often seen as prognostic or as a warning, and their interpretation was aimed at understanding the future. Roman history and legends offer many examples of this perspective. One of the best known is the dream that Calpurnia, Caesar's third wife, had the night before the ides of March when, according to Plutarch, she dreamt that the roof of their house had fallen, and Caesar had died in her lap (Plutarch 2013). Caesar, convinced by Brutus, decided to disregard the warning, went to the Senate, and was killed.

Inspired by the Greeks, Romans included dreams in literature and made them prove that the glory of Rome was the will of the gods. It is the case of Virgil's *Aeneid* which opens with

Aeneas' dream of Hector who warns him about the fire of Troy and tells him to take the Penates, the household gods, and cross the sea, after which he would build a new city (Virgil, *Aeneid*, II, 268–297). Thus, the dream proves that Aeneas was meant to end his journey on the coast of Latium and to become the heroic ancestor of the Romans.

With the advent of the Middle Ages, dreams continued to have great importance, were integrated in public life, and could communicate messages from the beyond. The Medieval preoccupation with dream interpretation occupied every social class. On one side, philosophers, theologians, and scientists try to explore the nature of oneiric life and classify dreams in different categories such as false and true, mundane, or divine. On the other hand, dream books and manuals of interpretation were appealing to common people who were more interested in the prognostic nature of dreams (Kruger 1992). These two trends were not always distinct. For example, referring to the situation in the Merovingian Gaul, Isabel Moriera maintains that, while some conservative views of dreams remained in the Christian church, there was a movement in the Merovingian church to accept the dreams and visions of layman (Moriera 2000).

The Renaissance continued with the importance on dreams. Dreams had a huge impact and became themes for renaissance paintings as well as scientific discoveries. Artists saw the possibilities for dreams to express the potential of man and to prove their worth. Sleep was the avenue to attain a freed soul that could enter a relationship with the beyond. Raphael's painting of *The Vision of a Knight* reveals that dreams could also confront us with choices. The painting reveals a young knight who must choose between two maidens representing virtue and pleasure. Anticipating Freud and Jung, some renaissance painters entered the world of the pagan and the erotic while other writers were attempting to reconcile their admiration for Greece/Rome with that of Christian teachings (Ruvoldt 2004).

Until the Renaissance, Western culture maintained the connection between the world of matter and the world of spirit, between the visible

and the invisible. Starting from the Scientific Revolution in the seventeenth century, this connection faltered. The cartesian dualism, in separating *res cogitans*, which dealt with the mind, from *res extensa*, which dealt with the body and matter, created a split between subjectivity and objectivity. Only *res extensa*, which is measurable, can be the object of scientific research while the realm of the subjective becomes questionable. Dreams fall in this second category and can deceive.

Enlightenment goes along with this idea. The *Encyclopédie* from Diderot et D'Alembert includes the voice "dream" only to say that dreams are tricks of imagination that pertain to the domain of metaphysics (Diderot and D'Alembert 1751). The Age of Reason dismissed the irrational and the subjective, which were reintegrated in Western culture at the end of the nineteenth century. The discovery of the unconscious revived the interest in dreams, which were to play an important role in the psychodynamic approaches in psychology.

Modern Views

In the second half of 1800, the communication with the beyond took an unexpected orientation with the rise of hypnotism. The French schools of Nancy and Paris-Salpêtrière discovered that hypnosis could unveil hidden skills, traumas, and personality traits that were unconscious in the wake state. In this way, the beyond that had previously been located outside of the human realm was relocated inside the human being. This had a profound effect on Freud who attended Jean Charcot's lectures on Hysteria in late 1885 in Paris. When Freud returned to Vienna, he embarked on his lifelong commitment to psychotherapy. His years of working with the dreams of patients resulted in his masterwork, *The Interpretation of Dreams*, published in 1900. This seminal work reawakened the public's interest in the unconscious once again.

The studies on hypnosis had revealed the existence of an unconscious part in the human psyche, which was not accessible or only partially accessible to consciousness. Understanding the nature

and the dynamic of the unconscious and how it played a role in the development and healing of neurosis became Freud's life commitment.

To understand Freud's theory of dreams, it is important to mention his model of the psyche, which is based on the tension of opposite forces. On one side, there is the *id*, which is the unconscious and irrational drive that opposes the *super-ego*, that is, the agency that sets the moral standards, the limits, and the rules of behavior conforming to the societal values. The *ego*, which corresponds to the sense of self, acts as a mediator between the *id* and the *superego*. When the ego is confronted with anxiety that feels overwhelming, an automatic blockage of the information occurs in the form of a defense. Inspired by the way the immune system attacks pathogens, Freud suggested that the psyche provides a defense system against invading information that consciousness cannot process. Typically, when the conflict between the *id*'s drives and the *super-ego*'s rules overwhelms the *ego*, defense mechanisms protect the ego from excessive anxiety (Freud 1976).

Similarly, the dream work proceeds in a way that protects the ego from the anxiety generated by disturbing oneiric contents, thus guarding the sleep. When creating a dream, there is a censor at work, which could block out painful dream images and substitute less threatening ones so that our sleep could be unencumbered. For this reason, in Freud's view, dreams had both a manifest and latent content. The manifest content was the literal meaning of the dream, its actual images and story; it was the superficial layer that was disguising the latent content. The latent content was the real, deep meaning of the dream, the one that needed to be discovered through the method of free association where patients simply came up with any ideas that they had about the dream symbol or experience. In making sense of the association, the latent content hidden in the unconscious could emerge to consciousness, which explains why Freud saw dreams as the royal road to the unconscious. Understanding contents that had been repressed, displaced, and denied through defense mechanisms would start the healing process from neurosis, which Freud

saw as mostly caused by sexual repression, where the ego partially blocked out the *id*'s desire in order to restore the reality principle. Eventually, Freud's insistence on sexuality as the cause of neurosis led some of his followers such as Adler and Jung to leave and form new schools (Freud 1976).

Carl Jung differed from Freud in proposing a dual unconscious, one being a personal unconscious from birth on, contrasted with a collective archaic unconscious filled with universal images that could affect our lives. He called these images archetypes, which meant original imprints built into the psyche over countless generations containing our ancestral history. Jung saw the possibility of reconnecting to lost energies if one could integrate the dream world. Dream analysis played an important role in therapy since deciphering dreams meant understanding the messages from the unconscious. However, instead of the reductionistic Freudian vision, Jung introduced a teleological approach which focused on the purpose and the direction of the psyche. In this theoretical frame, understanding the purpose of the dream was more important than finding what had caused it.

Dreams present to the dreamer a new vision that often offers a compensation for conscious thoughts and feelings. They can also indicate a direction towards further development and guide the dreamer in life. They could also clarify objective reality or have a prognostic side. In Jung's view, dreams are an important part of the dialogue between conscious and unconscious. Their symbolic language does not disguise repressed drives but, rather, enriches consciousness with new and multilayered meaning. Symbols, which are part of the language that the unconscious uses to reach consciousness, are evidence of the creativity of the unconscious. Even when they refer to personal life and experiences, symbolic images in dreams maintain a link with the collective layer of the unconscious, which is a reservoir for untapped potential and creativity (Jung 1963).

While Freud was trying to unveil defense mechanisms and understand the hidden content of dreams, Jung thought that dreams did not have a hidden content. Understanding the dream

images meant to reconnect with the deeper layers of the unconscious and undergo a process of transformation that he called individuation process: the process to become oneself.

Joseph Campbell, the mythologist who taught at Sarah Lawrence College, was influenced by both Freud and Jung and relayed how important it was to reconnect to the infantile unconscious where potentialities existed in the magic of childhood with all its mythological creatures and “goldens seeds” (Campbell 1949). In speaking about the potential and possibilities of the unconscious, Campbell stressed the creative power of dreams and stated that, “If only a portion of that lost totality could be dredged up into the light of today, we should experience a marvellous expansion of our powers, a vivid renewal of life. Moreover, if we could dredge up something forgotten not only by ourselves but by our entire civilization, we should become indeed the boon-bringer, the culture hero of the day—a personage of not only local but a world historical moment” (Campbell 1949).

The symbolic and psychodynamic perspective on dreams dominated the first half of the twentieth century. Then another trend emerged, which focused on the biological origin of dreams. The research on sleep and the brain came up with the hypothesis that dreams are created by the brain and pertain more to the world of physiology than to the one of symbols. Contemporary theories of dreams continue this view and perfect it with the support of new technology.

One of the leaders of this perspective was Allan Hobson, a dream researcher from Harvard, who saw dreams in a much different way than the psychoanalytic schools. His theory, which was called the activation synthesis model of dreaming, claimed that neuronal circuits in the brain stem become activated during sleep and that the brain tries to interpret and make meaning from these signals, henceforth the strange dream images and paralyzing situations during sleeping. Intense emotions, illogical content, sensory impressions, uncritical acceptance of dream events, and difficulty in remembering are all characteristics of REM sleep. Also, Hobson talked about “garbage can sifting,” which attributes to the brain the ability to select useful memories. In fact, the brain can

only retain so many memories within the hippocampus so that it must choose and select which memories to keep and which ones to discard (Hobson 2002). In this perspective, dreams do not conceal hidden meanings nor guide human consciousness in search for meaning. However, towards the end of his life, Hobson conceded that some dreams could be meaningful and relevant for personal life.

The Possible

The history of dreams, from the ancient civilizations to the psychodynamic and symbolic approaches, shows the human desire to create a connection with another dimension of life, one that, being spiritual and unconscious, can inspire human actions. The possible in dreams is essentially connective to the potential of transformation that they convey and to the creativity that they enhance. Their symbolic language is creative by definition, as symbols have multilayered meanings and require knowledge and imagination to be understood. Moreover, be it through their prognostic aspects or through their visionary suggestions, they have inspired human creativity and guided human lives.

The Jungian model is particularly useful to understand the possible in dreams, as for him dreams are the expression of both the personal and collective unconscious. On the personal level, they portray the dynamic of complexes while on the collective level they convey a universal message through archetypal images. The so-called big dreams come from the collective and archetypal level of the psyche. Those dreams can determine momentous changes in life and inspire creativity. Jung believed that dreams focused on the creative, prognostic, and teleologic potentials of mankind. One could say that dreams are creativity in action.

Jung introduced the concept of synchronicity which meant that ideas or premonitions could be validated in an external reality. Examples of scientific discoveries conveyed by dreams or synchronistic events are not rare. Jung and his colleagues related the following examples. Friedrich Kekule, who was a nineteenth-century

German chemist, had a dream that depicted a snake with its tail in its mouth. At the time he was contemplating the structure of benzene which left him frustrated. He interpreted the dream to mean that the benzene molecular structure was that of a closed ring. Elias Howe in 1845 dreamt of cannibals attacking him with spears that had a hole at their tip. He realized afterwards that this was the solution of how to complete his idea of the sewing machine with the thread going through the eye of the needle. Robert Louis Stevenson came up with the idea for Dr. Jekyll and Mr. Hyde from a dream that he had after contemplating man's dual nature (Jung 1964).

An interesting case that shows the inspirational role of dreams is the one of Niels Bohr who won the Nobel Prize for his work on the atom. Bohr had a dream that presented the image of a core with electrons spinning around it. This dream led him to discover the structure of the atom (Bohr 2008). Concerning Jung, he had dreams which led him to delineate his theory of the archetypes and the collective unconscious (Jung 1963). If these scientists and inventors had not followed their dreams and paid attention to the hints from the unconscious, the progress of humanity would have had a different course.

There are several instances of dreams adding to one's imagination and creativity in the world of music. Keith Richards of the Rolling Stones woke up one morning and from a dream understood the guitar riff for the song, "I can't get no Satisfaction," which he completed with a Gibson Fuzz-Tone Box, a recent invention which made an electric guitar sound like an organ (Richards 2011). Paul McCartney, of The Beatles, related two songs that were influenced by dreams, the first being the most recorded song ever, *Yesterday*, which has been covered over two-thousand times by other artists. He woke up one morning and had the music for the song. He was so struck by how beautiful the song was that he was convinced that he could not have possibly written it by himself (Bulkeley 2016). Also, another famous song, *Let it Be*, came at a time where McCartney was contemplating the end of The Beatles, but he desired for the band to continue. He dreamt that his mother, who died when he was 14, came to him and, in regard to The Beatles situation, said

simply, "Let it Be" (Oreg 2016). Regarding the relationship between music and dreams, Sting has said, "I think that any artist who ignores their dreams is ignoring half their creative potential" (Bulkeley 2016).

In 1963, Roy Orbison wrote a song called *In Dreams*, which was inspired by a night vision about the fact that he could only be with the one he loves while asleep at night. He woke up with the idea and the music for the song. David Lynch borrowed this song for his 1986 film, *Blue Velvet*, where the character played by Dean Stockwell lip synchs the song enlightened by a work light. Through this song, David Lynch was revealing the Freudian repressed contents in dreams and yet at the same time the Jungian orientation to the shadow which needs integration.

All these examples of how dreams have inspired creativity and guided artists and scientists towards new discoveries show that the unconscious offers unlimited potential. If human beings could accept that the unconscious is wiser than the conscious mind and that it is a treasure trove of information, this would be invaluable both to the individual and the society as a whole. Jung showed how fruitful the dialogue between unconscious and conscious can be. If we could follow his lead and integrate the unconscious messages that come through dream images, we could overcome the polarization between the opposites in the world. This would be an example of the potential of possibilities for all of us.

Dystopia

Maria Laakso

Tampere University, Tampere, Finland

Keywords

Dystopia · Dystopian fiction · Future · Possible worlds

Definition

Dystopia is a literary genre that displays terrible and unpleasant worlds, conditions, and societies often placed in the (near) future. Dystopias do not merely imagine possible future conditions but also mirror the existing reality. Dystopian literature criticizes trends and flaws in the contemporary society (Baccolini and Moylan 2003, 2–5,

Mohr 2005, 28). This duality is one of its most identifiable genre features. Dystopias are often considered as warnings about what will happen if a given practice or trend continues: thought experiments on the outcomes of present actions.

Introduction

Dystopias are often thought to be the ultimate opposite to *utopia* that visions a perfect society. Despite the evident difference between the two, most theorists in the field consider dystopia to be closely related to the utopian writings. An opposite to utopia would be *anti-utopia*, depicting an entirely flawed society, but as a literary genre, dystopias operate between these historical antinomies of utopia and anti-utopia. True, dystopias offer the worst possible future scenarios, but as dystopia theorist Tom Moylan (2000, 147) reminds, they oftentimes affiliate with a utopian tendency to maintain a horizon of hope: at least there is a possibility to resist and change the unwanted trends and practices. Dystopias are therefore often conceptualized as a dark version of utopian writing.

The prototypical dystopian narrative is a novel that begins *in medias res*, within a nightmarish society, which is introduced to the reader through the focalization of a protagonist. Classic dystopias like George Orwell's *Nineteen Eighty-Four* (1949) and Aldous Huxley's *Brave New World* (1932) construct their plot around the counternarrative of resistance; a suffering and alienated individual or a group of individuals rebels against the system (Moylan and Baccolini 2003, 5). In the contemporary culture, however, there are various dystopian subgenres and genre hybrids. Today, dystopia covers not just literature but all narrative arts – especially forms of popular culture, such as movies, TV-series, and comics.

Utopias and Dystopias

Despite its gloomy appearance, dystopia is closely connected to *utopia*, an ancient literary genre that imagines perfect and desirable societies (Suvin 1990). Both genres envisage possibilities for the contemporary world order: how to organize the

human world for better or worse. The term utopia is a derivative from ancient Greek, the literal translation being no-place (ou=not, topos = place), and it was first used by Thomas More in his famous *Utopia* (1516). The term ironically reminds the reader of the unreachable nature of a perfect society in the unperfect reality. However, the term carries a double meaning: not only Greek word *ou* (general negative) but also *eu* (good, ideal). (Manuel and Manuel 1979, 1). Eutopia is a term that many utopian theorists still use to discuss literary utopias (see Moylan and Baccolini 2003, 5), but terminology depends on the choice of the scholars. The word dystopia, in turn, is a neologism derived from Greek: *dis topos* – bad place. The term was first used much later than utopia, presumably by John Stuart Mill in his speech in front of the British Parliament in 1868 (Milner 2009, 827).

The historical gap between the two terms is noteworthy. The oldest utopian text is often considered to be Plato's *Republic* (c. 375 BC), which introduces an ideal society governed by philosopher-kings. The first modern utopia is More's *Utopia*, which gained many imitators regularizing a new genre in the sixteenth and seventeenth centuries: utopian fiction (Manuel and Manuel 1979, 1–2). Literary dystopias for their part were quite rare until the end of the nineteenth century. In the family of utopian texts, dystopia is a newcomer.

One obvious problem is how to classify utopian texts as dystopias or utopias. The simple answer is that utopias depict a world that is better than the actual world, and dystopias a world that is worse. Using this sharp distinction in practice is much more difficult than it sounds. Sometimes the works of fiction seem to change their generic compartment as time passes. Most obviously this can be seen with the old utopian fiction like Plato's *Republic* or Thomas More's *Utopia*. From the contemporary perspective, the ideal societies presented in these works appear to be antidemocratic and totalitarian – almost dystopian societies. Evidently, one can find dystopian echoes in utopias.

Vice versa, dystopias contain utopian undertones as mentioned above. Dystopian narratives even thematize utopian thinking frequently and show how easily every utopia is in constant danger of becoming a dystopia. In Margaret

Atwood's famous dystopian novel, *The Handmaid's Tale* (1985), the near-future United States has turned into a Republic of Gilead, theonomic and strictly patriarchal society, that brutally violates women's basic human rights in the name of religion. In the ethos of the text, the narrative's moral stance is obvious. The protagonist and the narrator of the novel, Offred, belongs to the suffering group of women who are forced to produce children for the ruling class. However, it is also evident that the new social order benefits some, and especially higher status men. Like the commander in the novel famously declares: "Better never means better for everyone (--) it always means worse for some" (Atwood 2010/1985, 224). Dystopias often balance between the two extremes, utopia and anti-utopia, and reminds us of the dangers of arrant utopias (Laakso 2020, 86; Moylan 2000, xiii.) As Ralf Dahrendorf (1958, 116) has noted, common structural characteristics of utopias are their uniformity and therefore also the dangerous absence of disagreement and conflict.

Utopian theorist Darko Suvin has claimed that "strictly and precisely speaking, utopia is not a genre but the sociopolitical subgenre of science fiction" (Suvin 2016 (1979), 76). The sociopolitical aspect of utopianism is easy to agree with, but it is common to see the term utopia used far outside on discussion of any kind of fiction. Lyman Tower Sargent treats utopianism as a form of *social dreaming* (1994, 1–3), "the dreams and nightmares that concern the ways in which groups of people arrange their lives and which usually envision a radically different society than the one in which the dreamer lives." Broadly understood, utopia diverges from literature to mean any future-oriented thinking that imagines possible world orders that differ from our own.

Dystopia, however, still most commonly refers to narratives that imagine dark and unwanted possible futures. Today, dystopia is one of the most popular genres in literature as well as in audiovisual popular culture. In comparison to the literary (or narrative) genre of utopia, the power relations between utopia and dystopia have radically changed starting from the twentieth century. Nowadays, rarely any published fiction belongs to the genre of utopia in the sense of depicting a good

place or society. Instead, novels, movies, video games, and TV-series are full of visions of pandemics, deprivation, exploitation, hunger, wars, horrifying technologies, and ecological catastrophes. Many hugely popular contemporary book and film series like *The Lord of the Rings*, *The Hunger Games*, and *Star Wars* have used dystopian conventions and made the story type of worsening societies and rebellion familiar to wide audiences (Isomaa, Korpua & Teittinen, xvi).

When considering the growing popularity of dystopias in the contemporary culture, one might wonder why dystopias are such an important part of our collective imagination. Why do we want to consume narratives on the possible destruction, devastation, or even the world's end waiting right behind the corner? The explanation to the growing popularity of dystopias is obviously complicated. One potential interpretation is that in a world facing the challenges of the climate change, the zeitgeist is inevitably dystopic, and hopeless future possibilities seem credible.

The other explanation lies in the taste of reading and watching of the contemporary audiences. Fredric Jameson has pointed out in his *The Seeds of Time* (1994, 55–56) that dystopias have a narrative, whereas utopias are mostly nonnarrative. Utopian societies are stable and need not to be resisted. If everything is fine, nothing must be changed. Dystopian societies, however, offer pleasurable challenges for the plot. Like Baccolini and Moylan (2003, 6) summarize: “Paradoxically, dystopias reach toward (–) the non-narrative quality of Utopia precisely by facilitating pleasurable and provocative reading experiences derived from conflicts that develop in the discrete elements of plot and character.” Dystopian narratives are highly tellable and therefore entertaining, touching, and approachable (Laakso 2020, 83). Classic dystopias like Orwell’s *Nineteen Eighty-Four* or Huxley’s *Brave New World* were hardly intended primarily to entertain, but regardless of their serious themes, they are exciting and emotionally addictive narratives (Isomaa et al. 2020, xvi; Baxter et al. 2014, 7–10). Contemporary dystopias offer not only fearful visions of the possible futures but also enjoyable experiences for the consumers hungry for an adventure. This partially

explains the ongoing dystopian boom in the contemporary culture.

Possible Worlds of Dystopian Fiction

Dystopia is a literary genre that portrays fictional worlds that are “worse than the ones we live in,” as Rafaella Baccolini and Tom Moylan excellently summarize in their introduction to *Dark Horizons* (Moylan and Baccolini 2003, 1). Today, however, this clear-cut definition raises questions. We live in the middle of climate change, and many other recent developments have brought dystopic worlds close to our own (see Isomaa, Korpua & Teittinen, x–xi). Who defines whether a fictional world is better than the reality we inhabit? How should the worlds of dystopian fiction be seen in relation to the actual world?

Worldliness is an essential dimension of any narrative. Narratives produce a *storyworld* or *fictional world* (the former contains also nonfictional narratives, the latter just fictional ones). Narrative theorist David Herman (2009, 106) defines a storyworld as “global mental representations enabling interpreters to frame inferences about situations, characters, and occurrences either explicitly mentioned or implied by a narrative text or discourse.” Worlds created in fiction are never ontologically complete, since they are just linguistic compositions (see Ryan 2019a, 74). The reader takes a few hints of the narrative text and constructs the full, vivid, and complete worlds based on her knowledge of the actual world. When we read Orwell’s *Nineteen Eighty-Four*, we assume that the world surrounding the protagonist Winston Smith and his struggle against the oppressive system is a complete world even though many details of this world and its inhabitants are delineated out of what is narrated. In a way, while reading fiction, we are all authors who imagine and create fictional worlds around the supporting structure of the text.

One workable approach to the worlds of dystopian fiction is the *Possible worlds theory*. Originally, the philosophical concept of *possible worlds* was adapted to literary studies starting in the middle of 1970s. The Possible worlds theory’s main idea is that a reality is a universe composed

of a plurality of distinct worlds. A central element in this universe is “actual” or “real” world, surrounded by “non-actual” or “possible” worlds. In the literary theory – or in a broader sense in theory of narratives – these possible worlds are fictional worlds created by fictions (Ryan 2019b, paragraph 1–3). In this sense, imaginary worlds of dystopian fiction like Orwell’s *Nineteen Eighty-Four* or Atwood’s *The Handmaids Tale* can be approached as possible worlds – alternatives to the actual world of the author and the reader. These worlds, however, should not be understood as “pseudo-objects on the page,” as utopian theorist Darko Suvin (1990, 76) reminds, but rather they exist “as a gamut of Possible Worlds in the imagination of the readers.”

The problem with the theory of Possible worlds applied to the dystopian fiction is the question of what lies behind the horizon of the possible. Two of the most influential narrative theorists of the possible worlds Marie-Laure Ryan and Alice Bell (2019, 5) have asked, are there also *impossible worlds* and if so, what are they in literature? Possibility is often associated with the laws of logic, but this is an unsatisfying answer in the case of fictional texts. In fictional worlds, anything is possible, and the real-world logic can always be stretched. As Ryan (2019a, 65–67) notes, an impossible possible world is an oxymoron. Instead, the possibility or impossibility of the fictional possible world should be analyzed with the concept of *distance*.

Distance as a notion obliges a point of reference. Possible fictional worlds are always opposed to the actual world we inhabit and where we gain our knowledge of the reality. As Ryan (2019a, 65) suggests, the distance between our world and storyworlds can be measured by certain (onto)logical rules that these worlds share. We should ask, how many rules describing the actual world are violated in fictional worlds?

The distance allowed or assumed by reader depends on the genre. In the case of children’s fairytales, we accept the possibility of magic, talking animals and other wondrous features. In the case of dystopian fiction, we typically expect a larger amount of realism. Genre features of dystopian fiction extend the distance of the actual world from the fictional world, concerning

societal issues like the form of the government, conditions of social justice, or freedom of speech. Many a time in dystopian fiction, the possible is not liberated from the rules and state of affairs of the actual world. The implicit genre agreement between the piece of dystopian fiction and its reader is that the depicted possible world is a dark future portrait of the actual world. Of course, exceptions exist. Contemporary dystopias are often genre hybrids between fantasy and dystopia or even fairytale and dystopia. In these cases, the idea of the possible worlds allows violation of logical rules of the actual world.

When considering possible worlds of dystopian fiction, *comparison* is always an inevitable part of the meaning making in the reader’s reading process. The comparison occurs between the actual world and the possible fictional world. In his theorizations on possible worlds of utopian and dystopian fiction, Mattison Schuknecht (2019, 236–237) uses the term *reference world*, a world that the alternative possible worlds encircle. Dystopian (as well as utopian) narratives are generically determined to be read by comparing and evaluating the actual world and the possible fictional world.

Conclusion

Dystopian fiction asks what may become of the world considering its present state, history, and ongoing evolutions. Most of the dystopian fictions are located in the future, but they might also be placed in the past or in the present. Often the temporality of the dystopian novel is not explicit and is intentionally left for the reader to decide. Sometimes the temporal state of certain dystopian fiction in relation to the readers’ present also changes. This has happened to the Orwell’s *Nineteen Eighty-Four* placed in the year 1984 as the title suggests. The year 1984 came and went and did not look quite like Orwell’s vision, yet even today, this dystopian classic is read as a possible future of humankind. Even though dystopian fiction often seizes current societal themes, dystopian narratives serve their mirroring function also for the readers who cannot relate to the temporal moment when a particular dystopia has been

written. Huxley, Orwell, and Atwood all wrote their dystopias as a critique of a sociopolitical situation that differs a great deal from the contemporary one. These narratives dating back several decades are still read, discussed, and used as reference points to evaluate ongoing processes. They still offer readers tools for reflecting the current political situation. The possibility of the dystopian fiction therefore seems to be built in a dynamic interpretation process into which the dystopian fiction invites its reader.

One way to understand the genre of dystopia is to treat it as a warning tale for adults. One often used metaphor for dystopia is a canary in the cage referring to how canaries were (ab)used in coal mines. When the canary dies, the oxygen level is dangerously low, and miners should save themselves. Dystopias can work as canaries, but still they are not detailed predictions of the future. Dystopian fiction can predict the future by imagining the ongoing tendencies, exploring things already happened or inventing something not yet existing. Yet dystopias are not simply warnings or predictions, but exciting and enchanting works of fiction that explore the possibilities we do not want to experience.

Definition

Emergence (EM) denotes a wide variety of phenomena – studied by numerous disciplines in natural and human sciences – where new processes, interactions, entities, and properties are claimed to be observed, characteristic for higher levels of complexity of matter and irreducible to their lower-level constituents. Playing central role in systems theory and theories of integrative levels, emergentism aspires to become one of the important categories within scientific explanation as it is understood today. As such, it departs from both strict holism and reductionism. Whereas the former assumes that we cannot infer anything concerning higher-level phenomena from the analysis of their parts, the latter argues there is nothing new about wholes, which would not already be present in their parts. Forging a middle ground between these two extreme positions, the term and the theory of EM designate the all-encompassing range of potentialities (possibilities) and dispositions of matter and its probable arrangements, which effect qualitative and irreducible originality and novelty of complex processes, entities, and properties, observed in nature. Despite its immense popularity as a conceptual tool, EM raises some challenges and objections. Because it is difficult to prove irreducibility, there is no agreement as to whether, in its basic assumptions, EM should be regarded as merely epistemological or ontological. Moreover, concerning ontological EM, there have been

several competing attempts at defining its main objectives.

Introduction

“Emergence” became a notorious philosophical term of art, appropriated by specialists in various scientific disciplines, as well as by nonspecialists in folk imagery and in common speech, where – moving in our mind’s eye among views at different scales – we realize and acknowledge that “more is different” (Anderson 1972). From bacteria forming a bi-directional vortex in a drop of water to vehicles forming traffic flow in modern cities, we discover new layers and strata of possible organizations of matter and of spontaneously arising structure and order. Mesmerized and mystified by the beauty of emergents, we nonetheless critically ask whether their irreducibility is a brute ontological fact, or rather simply the function of natural limitations in our scientific and analytic possibilities, knowledge, and understanding.

After a short historical introduction, this entry will provide a scientific definition and the classification of emergents, followed by the philosophical description of their basic characteristics. Next, it will discuss various species of EM – which shall reveal the difficulty of the critical analysis of spontaneous complex realizations of possibilities (potentialities) hidden in the reality of the universe we live in.

History of Emergence

The term “emergence” derives from Medieval Latin *emergere* = rise out or up, bring forth, bring to light (e.g., from a liquid by virtue of buoyancy), which is opposite to Latin *mergere* = to dip, or to sink. It was also used in late Middle French as *émergence*, originating from the verb *émerger*. But the origin of the EM theory goes back to Aristotle, who famously spoke about “things which have several parts and in which the totality is not, as it were, a mere heap, but the whole is something besides the parts [i.e., it is something more than the sum of its parts]” (*Metaphysics* VIII, 6 [1045a 8–10]).

The modern version of EM theory originated from the late nineteenth-century British empiricism. Witnessing impressive advances in chemistry and biology at the time, John Stuart Mill (1846) and George Henry Lewes (1875) realized that some of the reductionist explanatory bridges between these sciences and physics became untenable. They examined philosophical aspects of the “compositions of causes” and transition laws in cases investigated by chemistry and biology, emphasizing that some laws and causal explanations of higher phenomena are irreducible. Following this analysis, Lewes introduced, for the first time – in both scientific and philosophical contexts – the concepts of “emergent effects” and “emergents” (Lewes 1875, 412).

As the struggle between reductionism and the growing skepticism about its validity in special sciences (beyond physics) continued, emergentism was reinvigorated once again at the beginning of the twentieth century. This time, it was proposed in a more specific context of philosophical issues arising in biology, as a middle ground between the extremes of vitalism and mechanistic reductionism. Its major proponents were Samuel Alexander (1920), Conwy Lloyd Morgan (1923), and Charlie Dunbar Broad (1925). Although the theory they offered seemed to show the hallmarks of a valid and intriguing proposition, it came to be seriously questioned and radically rejected by the antiphilosophically and antimetaphysically oriented agenda of logical positivism and thinkers who stood at the origins of the analytic tradition in philosophy.

The most recent revival of emergentism came with the critical evaluation of the program of logical empiricism in the second half of the last century, accompanied by a new appreciation for metaphysics, originating from the conversation carried on by David Lewis (1969) and David Armstrong (1978), which was later joined by Saul Kripke (1980) and Willard Quine (1981), and the reinvigorated mind/brain debate, inspired by Karl Raimund Popper (1977), Mario Bunge (1980), John Jamieson Carswell Smart (1981), Roger Wolcott Sperry (1986), and Jaegwon Kim (1998). The conversation on irreducibility and EM they started was adapted in numerous scientific disciplines that introduce integrative levels and

systemic approach to the reality, such as chemistry, biology, psychology, or social sciences.

Emergents

Scientifically speaking, emergent processes, interactions, entities, and properties are defined in terms of an “unprecedented global regularity generated within a composite system by virtue of the higher-order consequences of the interactions of composite parts” (Deacon 2006, 122). They are characterized by the broken symmetry, i.e., the fact that the regularity present on underlying lower levels of complexity of matter is not present on higher levels of complexity, due to phase transitions, which bring novel types of regularity and order. This does not make the lower-order interactions irrelevant, but simply tells us that their effects, observable in higher-order phenomena, have been renormalized (Laughlin 2005, 44–45). This description can be regarded as a more articulate and precise contemporary expression of Aristotle’s observation that the whole is greater than the sum of its parts. See an example in Video 1.

First-Order Emergents

Emergents are traced in many natural phenomena (Morowitz 2002; Paolini Paoletti and Orilia 2017a), which oftentimes are classified on the three-order scale of growing complexity (Deacon 2012). Among the first-order emergents, a set of fundamental physical and chemical phenomena is usually brought to our attention, including mass, space and time (which are thought to be arising from Higgs bosons or strings), surface tension, friction, viscosity, elasticity, tensile strength, temperature, conductivity, chemical bonds, structures and chirality of macromolecules, etc. (McGivern and Rueger 2010). Many of them result from basic characteristics and patterns of behavior typical of molecules or other building blocks of entities and substances when taken in bulks (conglomerates).

Second-Order Emergents

Another set of examples of naturally occurring phenomena which both fascinate and puzzle human
